Gentlemen,—My notes under the above heading in this journal of August 11 and 25 seem to have been received with mixed feelings on "the other side." Mr. S. H. Horgan, the editor of "Process Notes" in the "Inland Printer," says it was hoped that I would give my impressions on the process plants I saw, and give my views of their methods, from which they could draw some valuable hints, and portions of my articles are accordingly quoted in an appreciative spirit. Not so, however, my Chicago friends, who seem to have taken my remarks rather badly, if I may judge by the "Engineer and Electrotyper." This journal heads its remarks: "Americans behind English!" (Don't forget the note of exclamation.) "It's too bad" (says this journal). "But that's where process workers in America have been placed by Mr. Wm. Gamble. And unless his verdict may be set aside Cis-Atlantic photo-engravers are likely to be considered back numbers by their English cousins across the water. Mr. Gamble did well to wait until he got safely on the other shore before rubbing it into Uncle Sam's platemarkers."

After this introduction, the "E. and E." proceeds to quote those parts of my articles which are least likely to be relished. Home truths are never very palatable. My remarks about the "rickety and ramshackle" cameras and camera stands seem to have touched the Chicago photo-engravers in a sore place, though I had in mind New York studios just as much as the Chicago ones when I wrote it, and it was in a leading New York studio where I saw a camera-stand "fixed up with wire nails and bits of string," and cameras which had to be trued up with wedges.

I am next taken to task by "Professor" Algono in this same journal. Mr. Algono says my statements about the equipment "in the majority of the photo-engraving studios of the United States are so utterly opposed to facts that it seems ridiculous to accord them even the attention of a contradiction." It is thought that I have singled out some small plants and ignored the "large and finely equipped plants" which it is admitted I inspected. I would, however, say that I did not visit any small plants. I had not the time to visit any but the most representative ones. Of course in a comparatively short article I had to generalise, and I could not state all the good features as well as the bad ones concerning each plant. I am, however, describing some of the more important concerns individually month by month in "Process Work," and I do not think it will be found that I have neglected to give the meed of praise where it is due.

I suppose Mr. Algono has not visited Europe, or he would have indicated in his article how far American studios are superior in equipment to European ones. I submit that if he has not seen the inside of our studios here he is not in a position to know whether the American equipment is efficient, and, for anything he knows, he is living in a fool's paradise. American visitors have frankly confessed to me that they could not have believed that their country was so far behind had they not had the opportunity of judging on the spot the work and the methods of European process workers.

The same remarks are sufficient answer to E. E. Medine, the

superintendent of the Crescent Engraving Company's plant in Chicago. He is a young man (judging by the portrait accompanying his letter), and he writes with all the self-assurance of American youth. He admits he has never been on the other side of the pond, but says he has "wasted considerable time and money buying and reading the British publications on photo-engraving." He goes on to say: "A careful study of British journals and publications, however, has failed to disclose any intelligent ideas regarding their advancement in photo-engraving. Their literature reveals nothing of importance that has not been originated in America; and as for elaborating on the processes we employ in this country, I will say that the specimens of process work, especially half-tone and three-colour work, shown by European publishers, are usually very poor, and do not stand on a par with the work produced daily in our engraving plants."

This is pretty "high falutin'," and I do not suppose anything I can say will convince this young man that he is wrong. He will find it out as he grows older. I would like to tell him, however, whether he believes it or not, that there is not a single process being worked in America to-day that did not have its origin in Europe. The half-tone process, the three-colour process, and zinc etching were not invented in America, and the man (an Englishman) who discovered the enamel process admitted that he got the idea from an old "BRITISH JOURNAL Almanac." I have always given all honour to such men as F. E. Ives, Max Levy, and other pioneers of American process work, but they themselves would be the last to subscribe to the accuracy of such a wild statement as is made by this reckless young writer.

There is no question about it that America, taken as a whole, is very far behind Europe in the equipment of photo-engraving shops, and I thought I was doing my friends on the other side good service in pointing this out. I give all honour to the men who turn out such excellent work as is undoubtedly done in America, with the very poor appliances furnished them.

WILLIAM GAMBLE.

THE PERMANENCY OF MATT COLLODION PAPER.

To the Editors.

Gentlemen,—Matt collodion papers being printing processes now largely used for better class professional work, I think a discussion in your correspondence columns as to the permanency or otherwise of these processes would be very desirable in the interest of users.

We who have adopted Matt C.C. as a printing process know only too well the extreme care required in handling to produce prints free from blemishes when mounted. But after every possible care exercised in the operations, and each print handled separately several times during subsequent washing, it has been my unfortunate experience that after prints have been mounted two or three days, yellowish spots make their appearance, and sometimes a print will go yellow all over in this short time. From observation I find this to occur most frequently in the damp and cooler season of the year, batches going through without spotting in warm, dry weather. The remedy, therefore, seems obvious—viz., tolerably speedy drying in a warmed room during the winter months. I have worked the process for three years, and, examining some prints done about that length of time, I find they are decidedly faded, and some gone discoloured in patches. The strength of fixing bath recommended is one which has received my attention as being open to suspicion—viz., 1 oz. of hypo to one pint of water—and I always use it somewhat stronger and fix for a longer time than advised. The rapidity with which the printed image reduces in intensity in the operations—and particularly have darkly-printed copies reduced if left for a short time in the fixing bath—must have been noted by users, and

seems to illustrate the somewhat feeble character of the image. Personally I have found that if a print be left in weak hypo for about two hours, spots at once make appearance.

It would be interesting if other users would relate their experiences.—Yours truly,

H. W. BUSBRIDGE.

2, Carisbrook Villas, Westcombe Hill, Blackheath, S.E.

[We shall be glad to have the views of other readers before commenting on our correspondent's letter.—Eds. B.J.P.]

DISTORTION WITH THE FOCAL PLANE SHUTTER.

To the Editors.

Gentlemen,—May I supplement the interesting article on the focal plane shutter, in your last issue, by the two enclosed prints illustrating the distortion produced by a horizontally moving slit. These were taken with the smallest slit and a low tension giving a nominal speed of 1-100 sec., and were produced in the course of

some experiments made by Mr. Carnegie and myself to test the effects produced by different shutters with moving wheels as objects.

The expansion produced when the slit moves with the image, and the contraction resulting from a reversal of the movement are both very well shown. The photographs were, of course, taken for the

purpose of illustrating the distortion of the wheels. A higher tension and a wider slit would have lessened it to some extent, but the speed could not have been much increased without giving marked under exposure, though we used $f/6.8$ on a fine sunny summer day.—Yours, etc.,

C. WELBORNE PIPER.

October 18, 1905.

Answers to Correspondents.

- * *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C."* Inattention to this ensures delay.
- * *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- * *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.*
- * *For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

PHOTOGRAPHS REGISTERED:—

- J. Bailey, 73, Shirley Road, Southampton. *Two Photographs of Four Generations of the Notable Page Family.*
- Charlotte C. Whyte, 4, Ardross Street, Inverness, N.B. *Photograph of the King, Lord Loyat, Sir Schomberg MacDonnell, and Mr. Baillie. Photograph of Sir Schomberg MacDonnell. Two Photographs of H.M. the King. Photograph of Royal Party Fifty-six in Number. All taken at Glenquoich Lodge, Inverness-shire, September 24, 1905.*

ANXIOUS.—As you have the negatives and do not know anything of the copyright in them, it is most likely that the copyright is lost. You can issue them, but you would not be able to prevent anyone from copying them.

HALF-TONE.—Will you kindly describe briefly in an early issue the method of making a half-tone process block from a photograph?—not a negative.—YOUNG PHOTOGRAPHER.

The process is too lengthy to be described in these pages, you had better consult a text-book. In "The Photographic Instructor," by J. I. Pigg (1s.), you will find a good brief description. For full working details see "The Half-Tone Process," by Verfasser (Iliffe, 3s. 6d.).

PLASTER CASTS.—Can you oblige us by putting us in communication with firm who supply plaster busts suitable for study in lighting, and accept our thanks in anticipation?—G. AND J. HALL.

Giuseppe Baldacci, 41, Hatton Wall, E.C., or Daniele Landi, 36, Charles Street, Hatton Garden, E.C.

PLATE SPEEDS.—It says in some advertisements that the speed of certain plates is increased by the use of a special developer—generally metol, I think—and I fail to understand how this can be.—Q. S.

The statement is perfectly correct for some plates. When the speed of a plate has been determined by the H. and D. method, using ferrous oxalate as a developer, it has been proved that several of the organic developers, as metol, will give a higher speed reading. In other words, such developers as metol will bring out of an exposed plate as much as possible and more than such a developer as ferrous oxalate.

G. H.—A plain floated paper, previously salted in a bromide bath, is used, and is not nearly so rapid as bromide. We should say are light is a *sine qua non*.

TITLES ON PRINTS.—I want to print on photographs and views that I take and expose for sale the names of places and what it represents. If you would kindly give me a little instruction, and where to obtain things suitable for the purpose, I shall be greatly obliged.—A LOVER OF THE WORK.

We should advise you to get the "Nameit" outfit as supplied by Richford and Co., Snow Hill, E.C. With that you will be

able to put the names on the negatives so that they print with the pictures.

LENS QUERY.—I have a studio 16 ft. by 12 ft.—good, uninterrupted north light. Would you advise a —'s lens $7\frac{1}{2}$ in. focus for general use in it. Should I get a good full-length cabinet with it? Would it cover well, so that at full aperture I could take children? The cab. portrait lens I am using is good, but I want a better. I thought if the above lens was suitable, I should be able to do away with the heavy half-plate studio camera and substitute a 1/1 plate field camera in its place, and should find it generally more portable. Would you advise retaining the ordinary studio camera and portrait lens, or do you think I could turn out satisfactory work with this lens.—A. E. FAIRWEATHER.

The lens mentioned is of very short focus for cabinet pictures, but as the studio is so small we do not see how you can use a longer for full length pictures. A lens of the focal length of the one in question is what is usually employed for carte portraits. We should advise you to retain the lens you have, and supplement it with the one you propose having, using the longest focus one whenever you can so as to obtain the better perspective.

COPYRIGHT QUERY.—I have recently photographed a "church choir," and half the proceeds from sale of the prints is to be devoted to the "Church Building Fund." I am anxious to have this negative made "copyright," and would like to know if there is anything to prevent me under the circumstances, and if I am bound to obtain permission.—J. RUSSELL.

If the choir sat at your solicitation, and you made no charge for taking the picture, the copyright belongs to you. If you were commissioned to take it, and paid for doing the work, the copyright belongs to those for whom you did it.

RESTORING DAGUERREOTYPES.—I should be pleased if you would kindly answer me under initials "H. W. B." in "Answers to correspondents" column of BRITISH JOURNAL OF PHOTOGRAPHY:—1. The address of any firm who specialise in the restoration of Daguerreotypes. 2. The procedure if I were to do the work personally.—H. W. B.

1. We cannot say. 2. The process is a delicate one, and space does not permit us to enlarge on the precautions to be taken. You should refer to an article in our issue of July 25, 1902. However, what you have to do is to remove the opalescent tarnish—the images have not faded—for which purpose clean the plate in alcohol, wash the surface in water until the "greasiness" has gone, and then immerse in a very weak solution of potassium cyanide until the tarnish is removed. The surface must on no account be touched at any stage. The plate is finally rinsed with distilled water and dried over a spirit lamp.

"VAPOUR" AND A. BROWN.—You can obtain information from A. W. Penrose and Co., 109, Farringdon Road, London, E.C.

DEFECTIVE NEGATIVES.—Could you explain the reason of small round holes in films of negatives after development?—J. H.

Probably the "holes" are clear gelatine, due to dust on the plate during exposure or air bells during development. It rarely happens that a plate is "pitted" through to the glass.

BOOKS ON THE STUDIO.—Can you tell me what books there are published on studio construction, which you consider best, and where I may obtain a copy; also price?—R. H. R.

"The Photographic Studio," by T. Bolas, 2s.; "Lighting in Photographic Studios," by P. C. Duchochois, 1s.; "Studio

Construction," 6d. You can obtain the above through your dealers, or from Dawbarn and Ward, Limited, 6, Farringdon Avenue, London, E.C.

DEXTRINE PASTE.—Would you be kind enough to give me the number of the JOURNAL in which the recipe for dextrine paste appeared. I made some paste to the recipe and have found it excellent in every way; I then cut out the recipe to paste into a book, and have unfortunately lost it.—A. J. S.

The formula appeared in our issue of June 2, 1905.

CARBON PRINTING TROUBLE.—I enclose you a carbon print, taken by the double-transfer process. A ground opal was used for the temporary support, and same was waxed with turpentine and beeswax solution. The print enclosed was stripped from the support two days after the operation, "double transfer," to ensure thorough drying. Will you kindly let me know the cause of the tissue not adhering to the final support, and the remedy to prevent this occurring again?—T. H. D.

The trouble may proceed from three causes. First, imperfect waxing of the opal plate; second, the double-transfer paper soaked too long in the warm water, so that the coating is dissolved off; third, the transfer paper, not soaked long enough to get it in an adhesive condition. The latter, we surmise is the cause of the trouble in this instance. In fact, we have little doubt about it. Soak the paper till it feels quite slimy to the touch, and then squeegee it on to the print. If the paper has long been made it will require a longer soaking in the warm water to get it into this condition than if it was newly made.

PHOTOGRAPHS ON WATCH CASES.—In an article on printing carbon photographs on "watch cases and the like," given in the JOURNAL on Dec. 2, 1904, it is recommended to use, instead of the ordinary temporary support, "foreign post" paper coated with a thin rubber solution. Can you tell me whether this rubber solution is the same article as is used for mending cycle tyres, etc., or whether it is another thing altogether. 2. Will the Nelson's Gelatine (Patent Opaque), sold at grocer's shops, do for photographic purposes, as well as "No. 1 Nelson's," as I seem to be unable to obtain this latter in less than half-pound packets?—H. M. K.

1. What is meant is unvulcanised indiarubber dissolved in benzole. Purchase a tin of rubber solution as sold at the indiarubber shops and dilute it with benzol to the consistence of rather thin treacle. Put the solution in a flat dish and float the paper upon it, and dry. 2. It is not stated for what photographic purpose the gelatine is required. It will do for some, but it is not suited for others. If the formula you intend to work by mentions the "No. 1 photographic," you had better employ that.

DAMAGED PHOTOGRAPH.—I have had an old photograph to copy for a customer. The photograph was tinted-coloured. The photograph itself covered by a cover glass. Photograph about $3\frac{1}{4}$ square inches. I took the cover glass away, and seeing a stain round the edges, I rubbed with a cloth. But the cloth being damp in a part it made the colour run. Now, I have thought that perhaps you might give me some information through the JOURNAL. If I rubbed the colour all off, could I have it re-coloured? The photograph appears to be at the back and covered with paper, coloured on the front, and covered with a glass. The picture is a very precious one, and any information would be gladly welcomed.—W. H. J.

Without seeing the picture we can hardly advise you. From your description it would seem to be a crystoleum. We should

think your best way would be to repair, with colour, the portion you have damaged, and then secure the picture as it was before.

DEPTH OF FOCUS.—What depths of focus respectively have a 5-in. and a 10-in. lens at an aperture of $f/16$, when focussed on point 10 in. distant in the first case and 20 in. in the second?—Focus.

This is a peculiar question, for in each case the adjustment is one for copying on a scale of full size, and the available depth is so small that the approximate rules, so useful under ordinary conditions, are not applicable. The following exact rules must therefore be used:—1. To find the nearest distance in focus, multiply the hyperfocal distance by the distance of the object, and divide the result by the hyperfocal distance plus the difference between the distance of the object and the focal length. 2. To find the farthest distance in focus, multiply the hyperfocal distance by the distance of the object, and divide the result of the hyperfocal distance minus the difference between the distance of the object and the focal length. The hyperfocal distance is always equal to the focal length, multiplied by the diameter of the stop, and divided by that of the circle of confusion. Taking 1-100 in. as the circle of confusion we find by these rules that with the 5-in. lens

$$\text{depth extends from } \frac{\frac{2,500}{16} \times 10}{\frac{2,500}{16} + 5} \text{ to } \frac{\frac{2,500}{16} \times 10}{\frac{2,500}{16} - 5}$$

or from 9.69 in. to 10.33 in.
so that the total depth is only .64 in.

With the 10-in. lens

$$\text{depth extends from } \frac{\frac{10,000}{16} \times 20}{\frac{10,000}{16} + 10} \text{ to } \frac{\frac{10,000}{16} \times 20}{\frac{10,000}{16} - 10}$$

or from 19.685 in. to 20.325 in.
and the total depth is .64 in.

The total depth is thus the same with both lenses, but it will be noticed that the near and far limits of depth are relatively nearer the lens in the second case. It is not likely that any lens will work exactly to these figures, and they are only rough guides.

ALPINE Photography according to the "Daily Chronicle"—"M. H. Muller, a Swiss photographer, of Berne, while taking snapshots on the Jungfrau, was overtaken by an avalanche, which carried his apparatus and himself some 250 yards without doing much harm to either. Later, on developing the plates, he discovered a fine photograph of the avalanche and himself tumbling down the mountain side. The avalanche had photographed itself."

*** * NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1906.

EDITED BY GEORGE E. BROWN, F.I.C.

THE forty-fifth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1st. This year's ALMANAC reached a total of 1,612 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1906 will also consist of 25,000 copies.

The lines followed in the previous editions of the ALMANAC will be maintained in general, but in a number of particulars the arrangement of the volume for 1906 will be modified to make it more than ever the book of universal photographic reference. The editorial article will deal very completely with the important subject of

PHOTOGRAPHIC COPYRIGHT,

and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The ALMANAC for 1906 will appeal to photographers all the world over as a daily reference guide in practical work. The standard matter and formulæ have been revised and added to where necessary, and wherever practicable new features of an informative nature added.

The publishers desire to draw the special attention of dealers and others to the fact that orders for the ALMANAC should be placed well in advance of publication; for the reason that, in all probability, the edition of 25,000 copies will again be exhausted before the date of issue, December 1.

EX CATHEDRA.

The Cape Town Exhibition. An Offer.

We recently published particulars of the International Photographic Exhibition to be held in February next in South Africa. The Cape Town Photographic Society is making every endeavour to ensure the success of the show, and it is hoped that a large entry will be sent from this country. In order to assist intending exhibitors, and to facilitate dispatch, we have arranged to receive and forward to South Africa all pictures entered for competition in this exhibition. Exhibitors will, therefore, only be put to the expense of carriage to and from THE BRITISH JOURNAL Office, 24, Wellington Street, W.C. The closing date for entries is January 13, and exhibits should, therefore, leave London by December 7. Exhibitors intending to take advantage of this offer must send their exhibits so that they are in our hands at latest by December 4, and should be distinctly marked "Cape Town Exhibition." We have on hand a supply of entry forms and these will be forwarded on application. On another page will be found brief particulars and conditions of the exhibition as affecting British exhibitors.

Christmas Orders.

With Christmas seven weeks from us, we have to prepare for the rush of work that season usually brings. In fact, many orders are now in hand for work required in time for posting abroad. The well-organised business is already prepared for dealing with the extra pressure of work. Daylight printing is out of the question, at any rate for orders that come in within the last two or three weeks, and, in the absence of special illuminants, bromide, or the slower gaslight printing papers, must be employed. We recently referred to the partial printing of P.O.P., the image being developed up to full depth by means of an acid hydroquinone or metol developer; but for a rush this method will not compare with the papers printed entirely by artificial light. Preparations should, therefore, be made, a supply of materials obtained in readiness, and some careful experiments made as to the best means of securing perfectly uniform results. There are many brands of paper on the market, and one should be chosen which will give the best results with the particular class of negative produced in the establishment. In working gaslight papers the main points to bear in mind are correct exposure and development with a strong, fresh developer. The professional worker will probably find it best to use these papers with a bright yellow light rather than in the open gaslight. If bromide papers are employed accuracy of exposure, uniform exposure for each print of a series, and development to the full in each case will produce prints of equal depth and colour. Rapid development, one to one and a

half minutes, and rapid fixation, not over ten minutes, with quick washing afterwards, go a long way to the production of good blacks and greys.

Price Lists. We have lying before us, as we write, several price lists from studios of different types, and the feeling forced upon us is that very much more might be done in their production to attract the public within the studio. Last week we printed an article dealing with the reception-room and its presiding genius, the receptionist. We pointed out that, broadly speaking, the effort should be to attract the prospective sitter within the premises, leaving the clever receptionist to secure or enlarge the order. It is questionable whether the very full and sometimes complicated price list really serves any useful purpose, particularly now that the various styles of mounts in use so vary the cost of the prints. Sitters invariably ask many questions as to price and style when they make appointments or come for sittings, indicating that the printed information has conveyed no definite idea to them. This being so, is it not worth while taking a leaf out of the book of the great advertising firms and, having some special line, call attention to that, and only that? Quality may be the specialty, or a particular style, or rapidity of production, or evening work by means of artificial light; but, if attention is called to the one point, and prices for dozens and half-dozens of the one line quoted, we think force will be gained by concentration. It would be almost essential to introduce from time to time new specialties, particularly in a town where the population is not frequently changing.

Does Cheapness Attract?

The question at once raises the old dispute as to the position of photography as a profession or a trade. We do not intend to discuss the question, thinking it sufficient to say that those who can run a studio on professional lines are well advised to do so; but that very many must perforce treat it as a trade, and adopt methods common to business where a manufactured article is offered to the public. As long as ladies have money to spend bargains will be hunted for, and ladies form a considerable portion of the photographer's clientele. With the very highest class of business the attraction of low price is not a consideration; and, in fact, it may then happen that a high price is an attraction. But where the bargain-hunting class of client exists, and they are attracted in the way indicated it is of the utmost importance to make the most of the position. Here the expert receptionist seconds the efforts of the one who framed the advertisement. The "ticket line" is only intended to open the door to further transactions—not in the future, but at the time. In arranging and advertising a special line, the utmost care must be taken to avoid an appearance of cheapness. It may sound cynical, but what many people like is to think that they are clever enough to get the best article at the price of the cheapest.

The Word "Photography."

The letter by Dr. Murray in the "Correspondence" Column this week raises an inquiry which has often occurred to ourselves, and it is one which at one time or another we have attempted to pursue further than the paper of Sir J. F. W. Herschel to which Dr. Murray refers. But we also have been unable to discover the words "photograph" or "photography" ante-dating Herschel's communication to the Royal Society. The readiest way to obtain a glance over the nomenclature of the earliest days of photography is to turn over the pages of the "Athenæum," which, for some years following 1839 discharged the duties of a

photographic organ. There we find Niepce's work described as "heliography," Fox Talbot's as "photogenic drawing," and only Herschel's as "photography." The now familiar name was used particularly in relation to Herschel for some time, and was included as a sub-section of the whole art of "photogenic drawing." It is not until 1843 that the latter phrase commences to be replaced by the word apparently first employed by Herschel. Considering the meagreness of literature ante-dating Herschel's paper, it is unlikely that any prior use of the words "photography" or "photograph" has been overlooked, and the natural explanation of the glib way in which Herschel let fall the words seems to be that they were the most natural Anglicisms—of a process and a product—to occur to a scientific man who was also a classical scholar.

THE "RESTORATION" OF DAGUERREOTYPES.

Professional photographers are sometimes called upon by their customers to copy a Daguerreotype portrait, the image of which is nearly obliterated, or, to use a more customary term, "faded." Bad as the state of the picture may be, it is usually highly prized by its owner, who may have heard that such pictures can be "restored." The photographer, perhaps, may have no idea as to how to do the work, nor is it surprising that the majority of the present generation of photographers should not be *au fait* with a process that became obsolete some forty or more years ago. Last week, in the Answers Column, we replied to a correspondent who very wisely wanted the address of someone who made a specialty of restoring Daguerreotypes, or, failing to obtain that, some advice on how to do the work himself. We say "wisely" advisedly, for it is within our knowledge that many valuable Daguerreotypes have been irretrievably ruined by people, knowing nothing of the exceedingly delicate nature of the pictures, attempting to deal with them.

Few, except those familiar with the process, recognise how extremely tender is the Daguerreotype image, although it is in reality the most permanent of all silver pictures. The image, it may be mentioned, is not supported by a film of any kind, nor is it protected by one, as in the case of a collodion or gelatine picture. It is merely on the surface of the metal plate, and can easily be removed with the finger, and a slight touch may be quite sufficient to leave a mark which no after-treatment will remove.

Briefly, the Daguerreotype process is as follows:—A silvered copper plate has its surface brought to an exceedingly high state of polish, i.e., until it is quite black. As a matter of fact, it is this black polish that forms the deepest shadows of the picture, and the higher the polish, the more vigorous the picture. This highly-polished surface is exposed to the vapour of iodine, then to that of bromine, and again to iodine. The iodide of silver is thus formed direct upon the bare metal. After exposure in the camera, the plate is submitted to the fumes of mercury, by which the image is developed. It is then fixed and afterwards "gilded"—that is, toned with gold.

Now, what takes place when a Daguerreotype "fades" is that the silvered surface of the plate becomes tarnished and the tarnish obliterates the image. But the picture is still there, and it is only necessary to remove the tarnish to make the portrait as good as it was at first, provided it has suffered no mechanical injury. If the picture was hermetically sealed, and kept so, so that the air did not obtain access to it, there would be no so-called fading. This sealing up the producers of Daguerreotypes were always careful to do by binding the picture, mat, and

glass together at the edges with goldbeater's skin, or a hard sized thin paper. In nine cases out of ten when a Daguerreotype has faded it has been taken out of its case, unsealed for copying, and then simply put back again without the trouble being taken to secure it against the atmosphere. Hence the deterioration, which always proceeds from the margin inwards. Often the centre of the picture is quite good, while the edges are nearly black. It is obvious that the image being in the attenuated form just described, and having no film to hold it as in the case of collodion or gelatine pictures, mechanical methods, such as polishing, are out of the question; and, therefore, chemical means must be resorted to in order to get the tarnish away. Cyanide of potassium is the agent to be employed, and we will now describe the manipulatory details.

The picture is taken out of its case and the old securing paper cleaned off the back, carefully avoiding any particles getting on the front. If there is any dust on the picture which cannot be blown off it should be allowed to remain, as it will be removed in the next operation. Its removal, even by a camel-hair brush, if it be of a gritty nature, would be liable to scratch the image, and a scratch once made cannot be eradicated. The next thing is to wet the picture evenly, and this cannot be done direct with water as the surface is very repellent to that fluid. The plate is first flooded with alcohol for a minute or two, and then put under a gentle stream of water from the tap, until all apparent greasiness is removed. Then, having ready a solution of cyanide of potassium, a little is poured over the plate and flowed backwards and forwards until the tarnish has been dissolved off. No definite strength for the solution can be given as the cyanide of commerce varies so much—from thirty to ninety per cent. The best way, therefore, is to make up a pretty strong solution and then add a little of it to some water, gradually adding more

until the tarnish begins to yield, and then allow time for its complete action. The solution may be used in a dish; but the better method is to pour it on and off, as then it can be applied locally, if desired. The tarnish having been removed—the picture restored—the plate is well washed under the tap, and finally rinsed with distilled water. If the final washing is with common water a thin veil is left from the lime or other impurities in the water. The picture is dried, and the drying must be done properly or streaks will be left. The method is this. The plate is held by one corner—say, the bottom left hand one—with a pair of pliers and flooded again with distilled water and drained from another corner, say, the right hand one. From this point the slope of the plate must not be changed. The flame of a spirit lamp is then brought under the highest corner, and as this dries the plate is gently raised so that the drying proceeds regularly downward. If there is a stoppage in the drying a mark will be caused which it is almost impossible to get rid of. In the drying, too, much heat must not be employed, or some of the mercury forming the image may be vapourised and the picture weakened.

The work being finished, it only remains to hermetically seal the plate and replace it in its case. This is done by binding the picture, the mat, and the glass together with a thin hard sized paper, or goldbeater's skin, as lantern slides are bound up. The best cement, perhaps, is flour paste; but gum should not be used, as when dry it is liable to split off the glass and metal. Most of the glass used for glazing Daguerreotypes was thick, and had its edges ground to give a tooth to the cement.

Although we have given very full details of the method of cleaning Daguerreotypes, we would strongly advise our readers, in view of the delicate nature of the image, not to attempt the work on a valued picture before they have experimented on one or two of little or no account.

HINTS ON PLUMBING FOR PHOTOGRAPHERS.

OUR readers will doubtless have noted a recent case reported in the JOURNAL when a photographer was mulcted in fairly heavy costs for damage done to other people's premises by the water from one of his sinks which had got stopped up. This stoppage of waste pipes is of frequent occurrence, and even large three-inch pipes are subject to it. Even if one does not damage other people's property, when no one is near and the sink overflows, there is certain to be a fair amount of deterioration to one's own place, and therefore it is advisable to take means of checking the nuisance.

Clearing Congested Pipes.

The small one-inch pipe frequently supplied to photographers' sinks is often stopped by small objects finding their way into the pipe and lodging at a bend, or by itself jamming. The longer pipes are most effectually made useless by a print floating on to the grating, or more especially by pieces of film cleaned off from glass. Apparently, the water that soon collects, instead of removing the print or film, keeps it in place by the weight of the water. The first consideration is to keep open the pipe, and the second how to prevent the recurrence of the trouble. A very good method for clearing pipes is to have a short length of rubber hose with connection for the tap. The hose is then placed on the tap, the loose end fixed into the plug-hole, and well wrapped round with an old cloth. The cloth and pipe is then firmly held down so that no water can get out of the pipe and into the sink, the wrappings of cloth making what is practically a water-tight joint. When these preparations are complete the water is turned on at full strength, and the pressure in all but the most stubborn cases removes the obstruction.

The Plumber's Force-Cup.

This rough-and-ready method is obviously of no use for the bigger waste pipes. In the case of an obstruction in these pipes a long cane will usually remove the source of the trouble. Frequently, however, the photographer will send for a plumber to do the work, and incidentally to charge as much as possible, not only for removing the difficulty, but also for going to the shop for some necessary instrument (it is most peculiar, but they all do it). His calling in the plumber adds up, and would easily be saved by buying the apparatus the plumbers use. All ironmongers sell them, or will order them; they are called force cups, and are like an extra strong sucker. The price, which is saved the first time the arrangement is used, is one shilling for the small size used for one-inch pipes, one shilling and ninepence for the intermediate size, and three shillings and threepence for the professional article with long handle. This long handle is in the case of a bad stoppage very useful, for one gets so much more leverage. The method of using this little instrument is to place the indiarubber cup over the plug-hole and press down until the cup is flat on bottom of sink, and the water is expelled from the cup. It will now be found that it is almost impossible to move the instrument, and it practically cannot be done until the pipe is free and air admitted from the other end of the tube. To clear the pipe the handle attached to the cup is forced sideways, and very soon the suction will remove any impediment to the flow of the water.

These methods, however, remind one of locking the door after the horse has gone: prevention is better than cure, and though it is almost impossible to guard against stoppage caused

through the congregating of matter in the waste pipe itself, yet the most frequent cause of disaster in photographic establishments—that is, prints, paper, and films stopping the outlet from the sink itself—can be easily circumvented.

A Simple Safeguard Against Overflow.

With large waste pipes, a wire cage shaped like the half of an egg, and with two or three long wires to drop through the holes of grating and keep the cage in position over the pipe, will easily prevent the stoppage. With earthenware sinks with small holes, the prevention is not so easy, the small cage usually used frequently being stopped. It is, however, obvious that a small cage is not a necessity; a large one might just as easily be arranged, and will be more effective. These cages, however, are not always convenient, and frequently get in the way, or get mislaid or get broken, when dishes are moved in the sink, so that when possible the following is advised:—Beside the ordinary waste pipe an overflow pipe should be fitted to the sink, with the entry to it about one inch lower than the side of the tank. This entry may well be at some distance from the ordinary plug-hole. We should advise that the overflow pipe be at least equal in diameter to the supply pipe, and that it join the latter at about two feet below the plug-hole. It will thus be seen that in the event of the plug-hole or of the first two feet of the pipe being stopped, it is impossible for the sink to overflow. This pipe is most easily fixed to wood sinks lined with lead; but it is easy to get earthenware sinks with the overflow outlet bored in the side, and the certainty that even if prints do get loose, the sink will not overflow is worth some little trouble.

We recently had damage to ceiling and wall that cost a twenty-pound note for redecoration, so the cost of fitting cannot be pleaded. The whole thing will only cost about five shillings for each sink.

The Common Syphon in Emergencies.

There is another dodge that we intended to mention before when speaking of the short length of the hose. If not too short this hose can be used for emptying a full sink into some point lower than the sink without use of basins or buckets for scooping up the water. A large bath may be used, in fact, for relieving the sink. Put one end of tube into the sink, and lead the other over the side, but be sure that this end is longer than the one in the sink. Now place the end of the long tube into the mouth—or, preferably, into some one else's mouth!—and draw in the breath. You can easily tell when the water commences to flow, and can then place the pipe into the receptacle intended for the reception of the water. Of course this is a description of a syphon, and very useful it is, too. Recently, before we took precautions, a sink filled, and the washer or tap was defective, so water had to be removed. The nearest grating was over a wall, so, getting a garden hose, the water was taken up seven feet across a flat for fourteen feet, and then fell twelve feet. It took plenty of breath to start the syphon, but when started it acted splendidly. Another use for the tube when the sink is full and tap running without cessation is to place tube on tap and let the drippings run into some other outlet.

A Waterproof and Soundproof Floor.

For those who are willing to go to some expense to be assured that drippings from dishes, splashes, and overflows will not do any damage, the following can be recommended:—Each room where water is much used is floored, or, rather, the floor is laid, with sheet lead, carefully joined, and extending for two inches up the walls, making a big watertight tray. Not only does this remove all chance of damage to other property, but it deadens all sound—in fact, many offices are treated in this way solely with that end in view, and, moreover, the floor can be kept scrupulously clean, a consummation devoutly to be desired.

W. FOSTER BRYHAM.

THE WEEK IN HISTORY.

A Memorial of Daguerre.

TO-MORROW, November 4, exactly fifty-three years will have elapsed since the statue to the memory of Daguerre was unveiled in the little market-place of Bry-sur-Marne. It was at Bry that Daguerre spent his last days, and in the little cemetery he is buried. The memorial takes the form of a bust and pedestal, and on the latter one reads the inscription:—"A. Daguerre, Artiste, Peintre, Chimiste, Inventeur de la Photographie." The opening of the memorial was made the occasion of very liberal encomiums of the work of Daguerre, and if I had the mind I could fill up weeks and weeks of history with the eloquent orations of M. le Maire, and other speakers. *Sic transit gloria mundi*, the place and the statue are now as good as forgotten, and not one photographic tourist in a thousand probably that visits Paris ever makes the forty-minute journey from the Place de la Madeleine to Bry and has a look at the last home of Daguerre. If they knew of a book about it all perhaps they would read it as they take the night express to Switzerland or Italy, and so I name the volume which collects all there is to say of Daguerre: "*La Découverte de la Photographie en 1839.*" By Mentienné, formerly Mayor of Bry. (Paris: Paul Dupont, 1892.)

The Changing-box of Fifty Years Ago.

The idea of carrying a stock of plates ready for exposure appealed just as strongly to the photographic enthusiasts of the fifties and sixties of the last century as to your latter-day amateur, who must have his pocketful of cartridges, a magazine of plates, or a satchel of envelopes loaded with cut films. The early patents in photographic apparatus abound in descriptions of curiously-fashioned devices for dispensing with the all-convenient and still undisplaced dark slides. But as early as any,

I believe, was an apparatus devised by a M. Plaut, the subject of a note in "*Cosmos*" of November 7, 1852. M. Plaut's changer was evidently the forerunner of the changing-box, although, as far as one may gather from the unillustrated account of it, infinitely more cumbrous in use. But, at any rate, it was immeasurably more practicable than a piece of apparatus of which Fox-Talbot described in "*Cosmos*" a week or two later. The inventor of calotype outlined a "*Chambre de Voyageur*" within which the photographer should sensitise, then expose, and next develop his picture, a scheme of daylight operations on which many inventors have wasted time and money from that day to this; on which, indeed, as I see in the "*Patents*" column of the *JOURNAL*, protection is still claimed for apparatus as old as the hills.

The Pretsch Process.

About the earliest photo-mechanical process to come into any sort of regular use was that patented fifty-one years ago on November 9 by Paul Pretsch. The process, however, was applicable chiefly to line originals. Yet the inventor endeavoured to break up full-tone originals into a sort of stipple by producing a reticulation of the gelatine. As described in the patent specification, No. 1854, 2,373, a plate was coated with a mixture or emulsion of silver iodide in a solution of glue or gelatine, was rendered sensitive by bichromate, and exposed under a print or other object to be copied. The plate was developed in water until the image appeared in relief, and then washed in spirit of wine, and finally hardened by a series of processes applied to increase the relief of the gelatine image. From the relief a copy was made by electrotyping or stereotyping.

HISTORICUS.

PHOTOGRAPHIC SOCIETIES AND EXHIBITIONS.

SOME NOTES ON THEIR PRESENT POSITION AND MANAGEMENT.

VII.

A GLANCE at the list of forthcoming exhibitions announced from time to time in the *BRITISH JOURNAL OF PHOTOGRAPHY* must convince the most sceptical that these annual fixtures are more popular now than at any previous time. In fact, the number seems to be steadily on the increase, in spite of croakings in certain quarters that the provincial photographic exhibition has seen its best day. Changes undoubtedly have taken place in the conduct of the shows, but these have been internal, and, in most cases, for the good of the undertaking. Any one who has followed the progress of provincial shows for the past few years and has had opportunities of observing the prospectuses and the general management of the proceedings, must have been struck with the fact that the tendency has been to standardise not only the rules and regulations governing the exhibitions, but for societies to imitate the organisation of each other. In fact, with a slight alteration of names, one society's entry form would now very frequently serve for half a score other shows.

Exhibition Rules and Regulations.

If a dozen or more prospectuses of different exhibitions be taken at random, it will be found that a great family likeness exists between the rules and regulations of all of them. It will also be found that in the main these are similar to the rules adopted by a meeting of exhibition judges on April 11, 1900, and revised in June, 1903. These rules were drawn up for the benefit of the societies affiliated to the R.P.S., and are published annually in the "Red Book."

They can be taken as a good guide by any society contemplating an open exhibition for the first time.

One Class or Many.

Among the recommendations added to these rules will be found one that reads:—

"It is desirable not to have classes. Where there are classes their number should be kept as small as possible, and divisions, where made, should be entirely respecting 'subject,' such as portraiture, landscape, etc., and not such as hand-camera classes, enlargement classes, etc."

If the society is of some standing, and has held successful exhibitions in previous years, the first sentence contained in the above recommendation can certainly be acted upon with advantage. If, however, it is a newly formed society, or has had no previous experience in exhibitions, there can be no doubt that several classes and a goodly display of awards—medals or plaques—will attract a far bigger entry. The fact nevertheless remains, unfortunate as it may appear, many shows depend to a great extent upon the "pot-hunting" fraternity, and unless they are encouraged the exhibition is a failure.

The time is not yet ripe—and it still seems a long way off—when provincial exhibitions will be strong enough to dispense with medal awards altogether. At the present time, to offer the exhibitor—as a return for sending his pictures and entry fees—the bare honour of being selected and hung at a provincial show, would spell disaster.

The Entry Form.

When drawing up the entry form and prospectus, the secretary and committee will have to bear in mind the following points:—Number of classes in both open and members' classes—the latter in any case to be as many as possible for politic reasons. Lantern slide classes; the form the awards are to take, and how many in each class; the date of the show, which should not, if possible, clash with

any other exhibition; the number and names of the judges; and the length of time the show will remain open. The inexperienced secretary cannot do better, however, than write to the secretaries of all other societies holding exhibitions and ask for specimens of their entry forms, etc. With these as a guide a good idea of the right way to proceed will soon be gained. When these preliminaries have been dealt with, and the prospectus is printed, a list of the most likely exhibitors to whom they can be distributed should be obtained from secretaries of other societies by writing a courteous letter asking for the loan of copies of all available catalogues containing names and addresses of exhibitors. The method of sending out the prospectuses is also deserving of more attention than it gets. The forms are usually placed in envelopes and sent without further comment to the potential exhibitors. If the exhibitor is at all well known he is in receipt of a great number of these forms, and unless some particular attraction is offered will probably put the bulk of them in the waste-paper basket. It is no great trouble or expense, therefore, for the secretary to prepare a typewritten letter, and have it duplicated. If he personally signs them and encloses one with each prospectus, much more attention will be paid to the application for exhibits than if the form only is sent.

Advertising.

Before deciding on an exhibition, arrangements should, of course, be made for its accommodation, and when a suitable gallery or room has been secured, the event should be judiciously advertised. Editors of photographic papers are first approached, and a polite request to insert a preliminary notice and date rarely finds denial. The local papers should also be notified. The results of these announcements takes the form of applications for entry forms. If these are ready they should be at once dispatched and a note kept of the addresses, and when the time for sending in entries draws near, these applicants, and also the exhibitors whose names have been obtained from other sources, should each be sent a reminder on a postcard, or another entry form.

About this time, too, further paragraphs should be sent to the papers, indicating any special features of the show, and negotiations should also be entered into for obtaining the attendance of the mayor or other local bigwig to perform the opening ceremony. This will afford excuses for notices in the local press, and the formal opening of the show under these circumstances will probably be the best advertisement it will get. Posters and smaller bills are also very necessary. Endeavours should be made to arrange with the authorities to display the former on boards in special positions, such as near the gates of parks or other open spaces in the locality, and the fact that the local M.P., or the mayor, is announced to open the show, will greatly assist towards this end. Local dealers and other shopkeepers can usually be persuaded to display the small posters or bills in their windows, and each member of the society should be asked to see to the distribution of a certain number; each can usually get a few displayed, and the total will be a great help.

Sources of Income.

The sources of income open to the enterprising exhibition secretary for the benefit of the show are many. As, in nine cases out of every ten, the annual exhibition is run with a view to profit and not a loss, they are all worthy of attention. First, there are the entry fees. It should be quite definitely settled, when arranging the preliminaries for the exhibition, whether a selection committee will be appointed or not. If the show is a strong annual feature, and a large number of entries are anticipated, such a committee is an advantage; but if

is strongly advised that if any exhibitor's pictures are rejected, his entry fees should be refunded, otherwise the reputation of the society will suffer in the future. Secondly, advertisements in the exhibition catalogue. These can be either canvassed for by the secretary or his assistant, or the entire catalogue can be given to a printer who will undertake to produce the issue free and pay himself out of the advertisements he obtains for it. From the frequency this latter method is adopted it is clear that a profit can be made over the printing bill, and it is therefore advised that the matter be kept in the hands of the society. With an average price of £1 per page, and a couple of guineas for full-page advertisements on the covers, a handsome addition to the funds should be made if the canvassing is well managed. Every well-known photographic advertiser should be written to (the "B.J. Almanac" forms a good directory), and either a specimen copy of last year's catalogue or a dummy copy of this year's submitted. Full particulars as to number of issue, scope of exhibition, etc., and latest date for copy, should be given, and follow-up letters should be sent after an interval of a week if no reply is forthcoming. Local advertisements can be best canvassed for personally. Thirdly, trade stalls. If the show is a big one, certain well-known firms may send representatives. Usually, however, it pays best to offer the spaces to local dealers, who will then not only represent the big firms and derive profit from the advertisement, but will do much to boom the show among their customers before it opens. Fourthly, gate money and sale of catalogues. These, of course, depend on local circumstances, the weather, and to what extent the show has been boomed. Fifthly, commissions on sales of pictures, donations for medals, etc., and side shows. Lantern lectures, if well advertised, are always a draw, and it pays best in the long run if no extra charge is made. If space permits, however, a tea-room for afternoon visitors should be arranged. This can be let to a local caterer at a fixed price, and he will take all the profit he can.

Dealing with the Pictures.

When the time for entries approaches and the pictures begin to arrive, it will usually be found best to deal with them all together. On an appointed day, therefore, after the entries are all in, the secretary and his assistants (this is where the talkers and the workers betray themselves) assemble at the exhibition room, where all the cases and packages have been delivered, and, with the help of at least one professional packer, the pictures are removed from their coverings. Each worker should have an appointed task, and the secretary should see that he does it, or endless confusion will result. Storage for the empty cases and wrappings should be taken into account when hiring the hall for the show, otherwise there will be great difficulty in disposing of them until they are wanted again. As the exhibits are unpacked they are checked with the entry forms, which should be kept in alphabetical order (exhibitors' names) for ready reference. Their condition and a brief description of box should be recorded in space left for this

purpose, and a distinctive number should be marked on the case, the entry form, and the backs of all pictures from that case. This will be found very helpful for future identification when repacking.

Cataloguing.

The compilation of the catalogue should commence as soon as the entry forms are received, and the following method suggested by the writer some years ago has proved very reliable and expeditious in practice. A series of slips of paper about 12 in. by 2 in. are prepared beforehand. On them are written particulars of the pictures (title, process, name, and price) as given on the entry form. A space is left for the catalogue number, to be filled in later. By the time the boxes are unpacked each entry form should have attached to it one or more of these slips duly filled up—one for each entry. As the pictures are checked, its proper slip is attached by one end with a little gum or paste to the back of the frame near the top, and the remaining portion, with the particulars in view, allowed to hang over the front. The frames are then stacked according to classification, if there are classes, and finally hung. As soon as each wall or panel is hung, numbers are fixed to the pictures in proper rotation (these numbers should be small and neat) and the blank places on the slips of paper filled in with similar numbers. The slips are then torn off as many of the frames as are fixed in their final position, and sent to the printer. They form the printers' copy for the catalogue, and he sets the matter up straight away from them. Errors are far less likely with this system than with any other, and moreover the catalogue will be in strict agreement with the order of the pictures on the walls.

Hanging.

The plan adopted for satisfactorily hanging pictures in most exhibitions, and one to be commended, is to mark out on the floor a space equal to the wall space to be covered, and then arrange the frames in this space before putting them on to the walls. Each section of the walls can thus be quickly dealt with in turn, and the arrangement will usually give far more satisfaction than if the pictures are fixed straight on to the walls at first. If there are no classes, a good plan is to hang each exhibitor's work in a group if he sends in more than four pictures. The best height for the sight line will be about 5 ft. from the floor. This should represent the middle of the pictures "on the line." Frames—unless they are big—should never be higher up than 7 ft.

Judging.

The number of judges selected should always be odd. This is necessary to avoid a deadlock of opinion, which sometimes occurs when there are two or four judges. Three appears to be the best number, and the exhibition rules and regulations previously referred to will be found to meet all contingencies connected with the judging. The question of allowing the judges to know the exhibitors' names should be settled definitely, and quite the best plan is to supply each judge with an advance copy of the catalogue with full particulars. If sufficient faith cannot be placed in the impartiality of the judges chosen, they ought not to have been selected.

"HON. SEC."

WHEN DOCTORS DISAGREE.—In our issue of the 13th ult. we referred to statements made by Dr. George Lindsay Johnson in the "Daily Telegraph," conclusively shattering the old belief that the last optical impressions of a dying person were recorded indelibly on the coating of the eyes, and proved beyond question the impossibility of obtaining the image of a murderer by investigating or photographing the retina of the person murdered. The Rome correspondent of the "Daily Chronicle" now sends the following communication to that paper:—"An astounding discovery has been made by a distinguished Roman ophthalmologist, Professor Cyprian Martini. Readers of the 'Chronicle' will remember the assassination of Signor Bianchi, one of Italy's best-known criminal lawyers, who was defending Captain Modugno, at Perugia, on a charge of

wife murder at the beginning of last month. Professor Martini, in order to experiment with an improved ophthalmoscope invention of his, obtained the permission of the authorities to examine the eyes of the young university student Casale, who confessed to the murder of Signor Bianchi. By means of his instruments the professor affirms that he discovered a perfect profile of the murdered lawyer at the back of the retina of Casale's right eye, so clear was it that he was able to discern the exact position of Bianchi, the precise expression of his physiognomy at the moment of assassination." The account also states that several endeavours to photograph the image on Casale's retina were fruitless. Our readers who will refer to Dr. Johnson's communication will readily understand the reason of this.

DEVELOPMENT OF P.O.P. PRINTS.

THE formula published in our issue of October 20 in the report of the paper by Dr. Woolsey Blacklock, before the Gateshead Camera Club, has been tried by a writer in the "Pharmaceutical Journal," who expresses satisfaction with it, so far as to describe it as giving better results than any hitherto used. The following notes by the writer on his working of the process may be quoted in continuance of the directions given by Dr. Blacklock.

Development Precautions.

In my own experiments I selected the Ilford Special P.O.P. as being a quick and soft printing paper, which would yield a thin image with good detail to work upon, and gave this an exposure of about two minutes to diffused daylight, the negative employed being of full density and contrast. The print is put into the developer direct from the printing frame, no intermediate washing being necessary; in fact, it appears that the free silver nitrate of the paper plays an important part in the building up of the image. I found the development rather slow, it being quite ten minutes before the image had arrived at anything like full density. This was then fixed in the following:—

Sodium hyposulphite.....	1 oz.
Lead acetate	60 grains.
Water	6 fl. oz.

as recommended by Dr. Blacklock who, in his paper, makes no mention of any toning. The tone thus obtained is of a warm sepia character, and not unpleasing. Contrary to Dr. Blacklock's experience, I found that the developer became slightly discoloured after using it upon one print, and it did not appear to be advisable to use the same solution a second time. The back of the print became discoloured also, but the whites of the image remained clear, so that this was of no moment. My second exposure was made from the same negative, and was of about the same duration. Development proceeded just as in the first instance, but after well washing the developed print in flowing water I put it into a combined toning and fixing bath. Toning proceeded very slowly, probably due in great measure to the low temperature, and the finished result, though still warm in colour, has the purple tinge similar to that of a fully printed-out image treated in a like bath. I found that the prints toned rather quickly and unevenly in the ordinary sulpho-

cyanide toning solution, separate from the fixing, but possibly I might have been more successful had the toning bath had more time to ripen or if a minute proportion of sulphite, as recommended for the Ilford Special P.O.P., had been added to the toning bath as a restrainer.

Silver Nitrate as Accelerator.

It appears that the action of the developer, as recommended by Dr. Blacklock, is analogous to that of the intensifier used many years ago for collodion plates, which consisted usually of pyro, citric acid, and silver nitrate, the free silver nitrate of the P.O.P. taking an active part in the building up of the image. In order to test this I exposed another paper for about two minutes, and during the development added occasionally a few drops of silver nitrate solution, and found that this not only materially accelerated the development, but also added considerably to the vigour and richness of the image. The print thus obtained, and toned in the combined toning and fixing bath, is by far the best in quality I have yet obtained by this method. I would, therefore, suggest that a solution of silver nitrate of 5 per cent. strength should be kept at hand, and should the development be unduly slow, a few drops added from time to time until full vigour and density is attained. Extra care and cleanliness should be observed at every stage of the operations, or there is great liability of staining the paper, and, consequently, of ruined prints.

By Artificial Light.

In order to test whether similar results could be obtained at night by the use of magnesium ribbon as the illuminant, I made two exposures upon another negative, somewhat thinner in character, with complete success. For the first exposure, 12 in. of ribbon was burnt, being kept in motion during the exposure about 2 in. from the negative; this produced a visible image which developed up strongly, and produced a print quite equal to those obtained by the daylight exposures. The second exposure proved that 6 in. of ribbon was quite sufficient to produce an equally good print, probably even less would suffice, but in order to ensure equality of illumination, it would be necessary to cover the front of the frame with tissue paper or ground glass, which would probably necessitate the use of that quantity at least.

F. GOLDSBY, Ph.C.

A PHOTOGRAPHER'S ADVERTISING.

[A fortnight ago we published an account from "Printers' Ink" of more remunerative circle of patrons by local booklet distribution. advertising contemporary, deals in a general way with advertising deserving of study.—Ens., B.J.P.]

THERE is no good reason why the photographer should remain, as he does, in the world of outer darkness where advertising prevails not. For he has a splendid proposition. All it needs—saving the pun—is skilful development.

Portrait work forms the staple product of a photographic studio. Yet perhaps only one person in ten who really wants a new portrait ever gets up to the studio stairs and under the skylight. The rest procrastinate. Photographers continue to print plain business cards in church programmes or to dwell on their bargain prices in the scant newspaper advertising they venture upon. Little is said about the art of portrait photography or the latest styles in which pictures are finished. What photographer ever went the length of sending out decently-printed folders showing half-tone reproductions of his best work? Yet is there another line of business that lends itself so readily to illustration of this kind?

Business Through Sentiment.

The sentiment of the photograph is fine material for advertising. Death is continually taking people off, leaving relatives and friends

the way in which a photographic studio was introduced to a new and The following article, which also appeared in the columns of our as it may be undertaken by the photographer, but is none the less

without a likeness. Some families make a practice of visiting the studio yearly and having a group taken or individual portraits—a commendable practice that many other families would adopt if they knew about it. Then there are the babies. A baby changes so rapidly that its portrait ought to be taken every three months during its first year of life, and every six months up to school age. Weddings, birthdays, anniversaries, family reunions—all these are occasions that suggest photography to the photographer, but those who take part in them seldom think of the camera until too late. The advertising of a live photographer would be written in the form of little talks about these matters, suggesting uses of the camera and occasions when a visit to the studio would result in a valued memento. If the photographer were in a smallish town, and made a specialty of photographing residences, dinner parties, weddings, and similar gatherings, these would form another theme for good advertising talks. The artistic side of photography has never been presented to the plain people in its true aspects. If it were, by a photographer who knew his business, there would be less demand for the vulgar

over-retouched "picture" and more for the studied, natural photographic portrait—at twice the price.

You May Tell Your Customers How to Dress for a Photograph.

Information about his craft—that is the advertising need. How many photographers go the length of printing a folder telling people how to dress for effective portraits? Yet is any subject more live than this—has any a more direct bearing on satisfactory work? Not long ago the "Housekeeper" published an article on this subject, which covers it *in toto*. Reproduced as it stands, it would make a folder to mail to a list of the best people in town:—

HAVING ONE'S PICTURE TAKEN.

Colours in Dress Are of Utmost Importance—What to Wear When You Visit the Photographer's Studio.

Generally speaking, dark gowns should be avoided. Red, especially, is a colour to avoid, as it gives an intense black in the finished portrait. Even for the elderly ladies it is better to have something light and soft folded about the neck and shoulders. Sheer fabrics and good lace always look well in photographs if nicely arranged. Where possible a low-necked dress should be chosen, if the sitter is not too slender, since the lines of the neck and throat are the prettiest part of many photographs. Where one does not care to wear a regulation evening dress, one just slightly open around the throat is infinitely preferable to a high stock collar. A chiffon or mousseline de soie fichu is as artistic a thing as one can find, unless one be fortunate enough to have some delicate piece of old lace which can be arranged in somewhat similar lines. Some faces look more attractive when framed, as it were, by a large picture hat (ordinary hats are generally a mistake in photographs), and this, in combination with a low-necked dress, is not against the canons of good taste, though it might easily be so if the wrong kind of hat were used. An opera cloak edged with something light and fluffy is pretty thrown loosely over the shoulders, especially if one prefers not to have too much of the neck and shoulders

showing. Arranging the hair becomingly, so as to avoid any hard lines where it touches the face, is very important. The style of bringing a solid mass of hair low over the forehead is one that needs the most careful treatment in the world to prevent its ruining the picture. Indeed, it is well to avoid extreme styles (which are always ephemeral and look almost vulgar when they are no longer fashionable) in a photograph—not only in dressing the hair, but in what one wears to be photographed in. This is, of course, especially important in a full-length portrait, for, although we all get to like what is fashionable, however outrageous we first thought it, an exaggerated protuberance in sleeve, bustle, or any lines which are not those of the natural figure, become distasteful later on, and we feel inclined to burn up the photograph when we see it in our friends' houses.

Advertise Quality at a Good Price.

Prices should be a distinct theme in the photographer's advertising. But not competitive prices. The bargain idea has been overdone in photography, and the craft thereby put on a basis wholly wrong. People look for the lowest price now because they do not know what quality in a portrait means. If told in straightforward, informative advertising they would quickly see the point, willingly pay the price. In place of the old conventional dozen cabinets, all alike in their bourgeois finish, would spring up a demand for fine individual portraits of real artistic value. People do not always know what is best, and need education. Judicious advertising along quality lines would do for the photographer what it has done for many other business men—separate the bargain trade from that which is willing to pay for value. These plain advertising truths doubtless look trite to business men in other lines, where publicity has been developed logically. But the state of the photographic craft is so backward as regards advertising that they should be fresh and suggestive—so much so, let us hope, that they will be acted upon.

A CRITICISM OF THREE-COLOUR PHOTOGRAPHY.

II.

The Reproduction of Colour.

I MIGHT go on giving you numerous other examples, but we will now apply them to the case of colour photography. Taking them together, the reproduction of motion with the cinematograph, of relief with the stereoscope, and of sound with the phonograph, do they not give a blow to the sceptical aspect of the question? Do they not incline us to look more favourably on the feasibility of photography in colours in the professional sense? Do they not, indeed, take us still further and prompt the question, "How is it that we photographers, having done so much to instruct and please the world, do not also give in our prints the pink of the cheek, the hue of the eye, and the glory of the sunset on the mountain?"

Before answering this question, let us see what has already been done. Within a year of the discovery of photography in 1839, men's thoughts were turned to the possibility of fixing the colours of the camera image. Robert Hunt had already obtained results with a sensitised paper, showing that on exposure to diffused daylight under red, yellow, and green glasses, it became red under the red glass, yellow under the yellow glass, and green under the green glass. He also wrote as follows:—"Colour alone is wanting, and there are sufficient reasons for believing that in the progress of research we shall, before long, arrive at processes by which the delightful pictures of the camera shall be rendered permanent in all the beauty of those glowing tints which give to the fields of creation their exquisite charm and enchanting character." These remarks and experiments of Mr. Hunt are valuable as affording an example of the attitude of many early enthusiasts, both as regards the possibility of reproducing colours, and of the manner in which it would be accomplished. That is to say, it was fondly hoped, during those sanguine

days which immediately followed the first achievements in monotone, that a substance or preparation would be found which, on exposure in the camera, would permanently assume, or could by subsequent treatment be made to assume, the natural colours of the object.

The Work of Clerk Maxwell.

Years, however, passed without any real progress being made. But, in 1850, Clerk Maxwell, an undergraduate at Trinity College, Cambridge, studied the subject of colour. By 1855, and when but 24 years of age, he had conceived a complete system of recording colours by means of photography, as well as a method of reproducing them.

He says:—"Let it be required to ascertain the colours of a landscape by means of impressions taken on a preparation equally sensitive to rays of every colour. Let a plate of red glass be placed before the camera and an impression taken. The positive of this will be transparent wherever the red light has been abundant in the landscape, and opaque where it has been wanting. Let it now be put in a magic lantern along with the red glass, and a red picture will be thrown on the screen. Let this operation be repeated with a green and violet glass, and by means of three magic lanterns let the three images be super-imposed on the screen. The colour on any point on the screen will then depend on that of the corresponding point of the landscape, and by properly adjusting the intensities of the lights, etc., a complete copy of the landscape, as far as visible colour is concerned, will be thrown on the screen." Here we have the first conception—clear, definite, and incisive—of a method of reproducing colours, and in mentally looking back to this time, we can realise the immense step forward which it chronicled.

Photographic Records of Colour.

Sixteen years had passed, and had been spent by those who investigated the subject in the quest for a substance which would arrange itself, by the action of light into permanent compounds reflecting the multitudinous hues of nature, or in fact anything and everything which appeared in the least hopeful; like mariners getting sail to discover a port without charts or compass, and without even knowing its whereabouts, they were without a clue or a guide to help them. Clerk Maxwell, at one stroke, located the port, and gave the true course.

Sixteen years had passed, and the sensitive plate was universally regarded solely as a chemical means of recording gradations of light and shade. Half a century has since passed, and, speaking broadly, negatives are still regarded much in the same way. Clerk Maxwell, in one short sentence, gave us the more truthful statement, that our negatives are not records of light and shade; but records of colour. It is true that people knew their sensitive plates were only sensitive to violet rays—but this is a very different thing to the full recognition that negatives can form a true record of that colour, and can be used to reproduce it in its proper gradations as existing in the original. Clerk Maxwell further told us that by three such records—the others being red and green—all the colours of nature can be registered for future production at will.

Du Hauron's Colour Prints.

In 1870, Louis Ducos du Hauron pointed out, amongst many other applications, that, by use of transparent pigments whose colour is complementary to that which the negatives record, the system can be applied to the production of colour prints, and he introduced the process now developed afresh, that of superposing these carbon prints. At this time the Franco-German War began, and Louis Ducos du Hauron, though a born investigator, nobly left his experiments and went to fight in his country's battles. By 1879, however, he and some of his pupils, notably Artigue, of Bordeaux, and Albert, of Munich, had produced excellent specimens.

Since this time many new processes have been introduced, and we now have those of Ives, Prof. Joly, Benetto, Sanger-Shepherd, Lumière, and this year Dr. Koenig's Pinatype, besides many others. But none of these even remotely touch the problem from its professional aspect, and I will now endeavour to explain why it is they fail.

Clerk Maxwell's Methods in Practice.

The first of the two essentials which we found form the basis of the successful reproduction of motion, relief, and sound respectively, were simplicity of method, both in the means employed to form the records and in the reproduction. You will have gathered from my references to Clerk Maxwell that he taught us, and, I may say also, substantiated his teachings, by exact measurements, that both perfect records and the reproduction of natural colours are possible by very simple means.

Clerk Maxwell further taught us that we can, in fact, both record and reproduce all colours by three photographic impressions, and so we secure simplicity of method, the first of our two essentials. Let us put this clearly in another way. We can perfectly reproduce motion, so far as it is a question of sight, without having to reproduce the actual motions themselves. We can also perfectly reproduce the solidity and forms of objects, so far as sight is concerned, also, without having to make solid models. We can also reproduce the music of a hundred performers without the instruments themselves or copies of them. Clerk Maxwell showed us that we can include colour in our list, and reproduce by equally simple means the colours of nature. And here I will ask you to give me your best attention for a few minutes, as we are reaching the kernel of the subject.

While I am talking there are many perhaps who are recalling to their memories three-colour prints produced by one of the numerous processes already in vogue, and are saying to themselves—Do you mean to call these photographs in natural colours? Certainly not. A photograph in natural colours means the accurate reproduction of the colours as you see them on the ground glass of the camera, where they are true to nature, and highly idealised through being in miniature. I want everyone here to-night to fully understand that Clerk Maxwell's system of colour photography is in no way responsible for the crude results we are familiar with. The system is all right, but the methods and materials of carrying it out are defective. This brings us to the second essential to success—"Accuracy." At first sight it would seem that we ought to succeed in this respect, for we have the same accuracy of image on our ground glass which we find gives such admirable results with the cinematograph and the stereoscope, but the analogy is only superficial, for the accuracy of the photographic print, as distinct from the camera image, is only applicable to the outlines of the subject, and does not apply to the tones and colour values. You cannot alter the outlines of your image by using different plates, or by differences in exposure or development, or depth of printing, but the tone and colour values can and are altered by each of these alterations to almost any extent. It is precisely here that our colour reproductions break down. Our colour records are absolutely accurate in outline, but hopelessly inaccurate in their colour values. The pink of a lady's cheek requires absolute accuracy, both singly in each negative, and relatively to each other in the three negatives to become records of any real colour value, and the same applies to the prints. But the prints themselves by our present photographic methods, are just as likely to turn the pink into green.

Problems in Colour Reproduction.

We can now sum up our chief difficulty as follows:—The lens and camera give us on the ground glass accurately the natural colours of the original as well as the outlines, but both the recording negatives and the reproducing prints completely fail in accuracy except as one lucky chance in a thousand, or with very easy subjects.

Having localised the chief source of our difficulties, we must next find out why it is our negatives and prints, whilst giving us such absolute accuracy of outline, fail so completely in tone and colour values.

It is because the outlines are formed exclusively by optical means, whereas our tone and colour values are dependable, in addition, upon delicate chemical reactions (over which we have no adequate control) and human judgment. As long as we keep to mechanics and physics, it is not difficult to arrange matters so that we get automatic accuracy and uniformity of action, but directly we depend upon these delicate chemical changes or human judgment, however skilful, we introduce errors, and our colour process and prints, for these reasons, just in the one detail above all others where accuracy is required, fail us.

"Process" Solutions.

Let us now look round and see if we can find any way out of our difficulties, and here close at hand our attention is arrested by tricolour type printing, which is the one application of photography to the reproduction of colours which has any real professional value at present, and we soon find the reason of this success is that we have here a process in which the faulty methods of pure photography are to some extent got rid of and some degree of accuracy secured.

In three-colour type printing the prints are obtained with an ordinary printing press, and this means that we practically impress our paper with the full colour or with nothing, and do not attempt

to print gradations of colour. The gradations are there, of course, but they are produced by printing dots or stipple of different sizes in a given area, so that a greater or less portion is covered with the pigment and the remainder left white, as in a wood or steel engraving. In this way we remove the uncertainties of purely photographic printing, and secure accuracy so far as the dots on the printing block represents accurate colour records. But in order to make our printing block, we have first to secure what is called a screen negative—that is, one in which the gradations are formed by dots, as in the block. In the production of these screen negatives, as practised by photo-engravers at the present time, we have all the sources of inaccuracy, with others added, as occur in ordinary photography. It so happens, however, that the metal printing block is eminently fitted for retouching, for corrections, and for alterations, and the success of tricolour printing is founded largely on these two qualities—that is, first, the facility with which corrections can be made on the block, and, secondly, the blocks, once they are corrected and adjusted, become both accurate and automatic in the printing.

There is a very good illustration of this point. It is an example of tricolour printing by Mr. G. Symmons and myself, taken some time ago, in which an endeavour was made to get a correct reproduction without retouching, but less than two or three dozen negatives were taken before the negatives were sufficiently accurate for the purpose, but, once obtained, the block-making and printing became automatic.

"Irradiation" in Negative-making.

The question then arises, can we go a step further and obtain the same automatic accuracy in making the negatives, and to do this it is necessary, as I have explained, to get rid of the uncertainties due to human judgment and chemical reactions.

I have here a series of incandescent lamps, through which electric currents of different intensities are passing. Those who are sufficiently near will be able to see that the filaments of the brighter lamps look thicker than the others, and that the apparent thickness, in fact, is proportional to the brightness. You will particularly notice that the outlines of these thickened filaments have sharp edges. This effect is due to the light which forms the image of the filaments spreading in the retina of the eye, and is called irradiation. The same effect takes place in our photographic films, and you may make photographs showing these thickened filaments. Now in ordinary photography, as we have stated, the particular value of the gradation depends upon the chemical nature of the film, the exposure treatment during development, etc., and in ordinary screen-making, in addition to these elements of uncertainty, we have others added, due to the size and shape of stop, distance of screen, intensification and reduction, and so on, but this phenomenon of irradiation I have just shown you is a function exclusively of the physical nature of the film, and if you prepare a process screen so that its rulings are in contact with the film, you get a gradation of dots dependent exclusively upon the quantity of light reaching the film, and nine-tenths of your sources of error disappear. You have, in fact, the analogue of the waxed cylinder in the phonograph, except that although the light strikes the film vertically, it cuts its record laterally. There are numerous examples here illustrating this phenomena.

Here, for instance, are some large photographs, in which the tones are produced in the manner described, not exclusively so, because an ordinary process screen was used, having the thickness of the cover glass between the ruling and the paper. But notwithstanding this, in the case of these prints the gradations are quite independent of chemical reactions, of the time of development, of the composition of the developer, and human judgment, and, to a very large extent, also independent of the exposure.

We have, then, in the phenomena of irradiation a potential means of recording tone and colour values on our negatives, which is vastly more accurate and automatic than any system which has hitherto been published or utilised. There are, it is true, one or two other systems which eliminate chemical action, as in the highly scientific process of Prof. Lippman, founded on the interference of light.

The Need of Accuracy.

But what I wish to most particularly emphasise is that until you adopt some means by which the natural colours of the object automatically and accurately record themselves on the negatives, you cannot hope to realise photography in natural colours in the professional sense, and as far as I can see the only way to get such accuracy is to make the record a physical one, either with the aid of irradiation, such as I have indicated, or by some other similar means which research may discover. In the references we have been making to the employment of screens, we have been speaking so far in their relation to type printing, but they are equally applicable to pure photography. In type printing, the rulings of the screen must be fairly coarse, and certain conditions in connection with shadow dots and high lights, which are necessary, interfere with their accuracy, but in ordinary photography the rulings can be much finer, so fine, indeed, as to be invisible, and it is just with these fine rulings that irradiation has full play to exert its influence. There may be many here who are saying, surely you will not compare a process print with a good photograph? To such I would say, the defects of the process print are the defects of the rough methods of printing, not of the ruled screen.

[The lecturer here showed many examples in which the gradations were formed by irradiation, and stated that these gradations were not only equal to those given by the best ordinary photographs, but, if any thing, superior to them.] Here, for instance, is a reproduction of a very simple object—a white sphere. I do not think it is possible to obtain a photograph of this simple object by ordinary photography, which will compare, as regards delicacy and purity of gradation, with that obtained with the aid of a screen, and this test with a simple object is true in even greater force of more complex forms. Also in ordinary process work, in order to get correct screen action, we are practically confined to ruled screens and dots, but with irradiation we may employ curvilinear lines, stipples, patterns and textures of every description and of every degree of fineness, the one condition being the division of the screen into opaque and transparent spaces. Examine yourselves small steel engravings of statuary and other subjects, in which purity and delicacy of gradation are essential, and then see if you can find any pure tone shading which will compare with them.

In conclusion, let me remind you that the future is in the hands of the worker. Our theoretical knowledge is sufficient, if not complete. At the same time, the ratio, if I may use such a term, between work and the value of its results, depends upon the correctness of the lines upon which the individual expends his energies, and, as we have learned to-night, the lesson which the cinematograph, the stereoscope, and the phonograph, as well as many other triumphs of recent years, teaches us is that one of the conditions upon which future work must be based is that the methods of record and reproduction must be free from the inaccuracies which at present exist in photographic processes, inaccuracies which, while important even in ordinary monotone, form a fatal barrier to success in colour work, and I can express no more appropriate wish for those I am addressing than that they may be sharers in the commercial, professional, and pictorial triumphs, which the future undoubtedly holds in store in the domain of photography in natural colours.

E. HOWARD FARMER.

THE CAPE TOWN EXHIBITION.

ELSEWHERE in this issue we refer to our offer to British photographic exhibitors to receive and forward to South Africa all exhibits intended for the international photographic exhibition, to be held at the City Hall, Cape Town, in February next, under the auspices of the Cape Town Photographic Society. The following rules and conditions relating to the competitive classes are abridged from the prospectus of the exhibition. They are the only ones necessary to be observed by competitive exhibitors from this country. The entrance fee is 1s. for each competitive class, irrespective of the number of exhibits. Exhibits from other parts of the world than South Africa need not be framed, but must be mounted. Not more than one picture to be included in one frame or mount. The necessary particulars for catalogue must be given on the entry form, and a label bearing the name and address, also title or description of photograph, together with a number corresponding with that on the entry form, must be affixed to back of picture. Entry forms and labels will be forwarded, but any exhibitor may affix his or her own labels. The name of the exhibitor must not appear on the front of any exhibit, except lantern slides or stereoscopic transparencies. The rules and regulations of the "Conference of Judges," as published in the Photographic Red Book for 1905, will be adhered to. Arrangements will be made for the sale of pictures, if desired, subject to a commission of 15 per cent.

The International and Open Pictorial Section contains the following classes:—1. Landscapes. 2. Seascapes. 3. Architecture. 4. Genre and Figure Studies. 5. Still Life. 6. Lantern Slides any subject (sets of 3). 7. Stereoscopic Transparencies (sets of 3). 8. Stereoscopic Paper Prints (sets of 3). A silver medal is offered in each class.

There is also a section for scientific and technical photography, in which medals will be awarded at the discretion of the judges.

The society's gold medal will be awarded (in lieu of any other medal) for the most artistic picture, irrespective of class or subject, such picture to become the property of the Cape Town Photographic Society.

Pictures sent "Not for Competition" will be included in the Invitation Section.

The judges will be:—Pictorial Classes: Messrs. R. H. Whale (Art Master and Technical Instructor, Government School of Art), Vine Hall; and A. J. Taylor.

Genre and Figure Studies: Messrs. G. Crosland Robinson (Art Master, Government School of Art, and Diploma of Honour, Dresden Academy), J. J. Bissett, and W. Watson.

Scientific and Technical: Dr. R. Marloth, Messrs. H. E. Fripp, and W. Richmond.

Entry forms will be forwarded on application to The Editors, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, London, W.C. All exhibits intended for the competitive sections should reach this address not later than December 4.

THORNTON-PICKARD £100 PRIZE COMPETITION, 1905.

THE following is the list of prize-winners in the recent Thornton-Pickard prize competition. The organisers inform us that the competition has been a great success, and state that another competition on similar lines will be shortly announced for next year.

Class I.—For pictures taken with any of Thornton-Pickard cameras fitted with any pattern of Thornton-Pickard shutter, except focal plane: First prize, £10, Mr. D. Robertson, London; second prize, £5, Miss Ella Tomlinson, Chichester; third prize, £5, Miss Marion Silverston, Birmingham; fourth prize, £3, Mr. S. Short, Cardiff.

Six prizes, £2 each: Mr. S. Cato, Leamington; Mr. D. Dunlop, Motherwell; Mr. R. W. Dugdale, Gloucester; Mr. E. R. Housdon, London, S.E.; Mr. C. Phelps, Trinidad, B.W.I.; Miss Agnes Tomlinson, Chichester.

Class II.—For pictures taken with either pattern of the Thornton-Pickard focal plane shutter: First prize, £10, Mr. Graystone Bird, Bath; second prize, £5, Mr. J. S. Lancaster, Bournville, Birmingham; third prize, £4, Mrs. Mahony, Dalkey, Co. Dublin; fourth prize, £3, Mr. C. J. Waters, Epsom.

Class III.—For pictures taken with any of the various patterns of the Thornton-Pickard shutters, except focal plane: First prize, £10, Mr. Karl Wipplinger, Linz, A.D.; second prize, £5, Mr. J. W. Sagar, Burnley; third prize, £4, Mr. J. A. Symington, Kew; fourth prize, £3, Mr. J. J. Hartley, Colne, Lancs.

Six prizes £2 each.—Mrs. G. A. Barton, Birmingham; Mr. A. W. Cooper, Preston; Mr. E. O. Hoppe, London, E.C.; Mr. Ward Muir, Boro' Green, Kent; Mr. F. G. Price, Crumlin, Newport, Mon.; Mr. J. A. Symington, Kew.

Class IV.—For pictures taken with the Thornton-Pickard Studio shutter, used either in or out of the studio: First prize, £5, Mr. F. Brigham, Scarborough; second prize, £3, Miss M. Prentice, Glasgow; third prize, £2, Mr. T. Johnstone, Motherwell.

Exhibitions.

SHEFFIELD PHOTOGRAPHIC SOCIETY.

THE third annual exhibition of this society was opened at the Montgomery Hall, Sheffield, on Saturday last. Over 400 exhibits are on view, of which 180 are contributed by members of the society. The exhibition is in every way an excellent one. The opening ceremony was performed by the Master Cutler, Mr. Sydney Jessop Robinson. The judges, Messrs. F. M. Sutcliffe and C. Barrow Keene, made the following awards:—

Open Section.—Champion Class.—Any subject which has been previously medalled in open exhibition.—Silver-gilt plaques: "Tugging Home," Wm. Clayden, Plymouth; "November," Fred Judge, Hastings.

Landscape, Seascape, and River Scenery.—Silver plaque: "A Dusty Day," Arthur Marshall, A.R.I.B.A., Nottingham. Bronze plaques: "A Dutch Canal," James Gale, Wolverhampton; and "June," Jno. S. Atherton, Todmorden.

Portraiture, Figure Studies, and Animals.—Silver plaque: "The Artist," Thomas Heaps, Keighley. Bronze plaques: "A Jovial Monk," Wm. H. Foxall, Tunstall; and "Binding the Wheel," A. E. Coleman, Plymouth.

Architecture, Interior and Exterior.—Silver plaque: "A Norman Procession Path," Wm. A. Clark, Birmingham. Bronze plaque: "Until the Day Breaks," S. G. Kimber, Southampton. Certificates: "Water Gate Row, Chester," Dan Dunlop, Motherwell.

Flowers, Fruits, and Still Life.—Silver plaques: "Grasses," S. G. Kimber, Southampton; "Hops," E. Seymour, Watford. Certificate: "Iris," E. Seymour.

Lantern Slides (any subject).—Silver plaque: "The Town Cobbler," Rev. H. W. Dick. Bronze plaque: "Birch and Bracken," F. W. Banks, Southport. Certificate: "Kittiwake, Farne Island," Wm. Farren, Cambridge.

For Novices under fifteen years of age.—Bronze medal: "I'm A-coming," W. F. Pilch, Sheffield. Certificate: "Bolton Abbey," Jack Perrin, Halifax.

Members' Classes. Landscape, Seascape, and River Scenery.—Silver plaque: "Conisbro' Keep," Dr. H. G. Paterson. Bronze

plaques: "Whitby," Dr. H. G. Paterson (debarred); "The Lake," H. D. Parkin. Certificates: "Twilight," F. J. Roberts; "December in the Wood," Arthur Turner.

Architecture, Interior or Exterior.—Silver plaque: "The Old Refectory," F. J. Cribb. Bronze plaque: "Cathedral Square, Geneva," James R. Wigfull. Certificate: "The Ballroom Doorway," Jonathan Taylor.

Any Other Subject.—Silver plaque: "Is He Thinking of Me?" Arthur Turner. Bronze plaque: "Bluebells," Miss E. H. Tillotson; "A Grinder," Dr. H. G. Paterson. Certificates: "Dejection," H. D. Parkin; "A Sheffield Blade," Dr. H. G. Paterson.

Lantern Slides, Landscape, Seascape, and River Scenery.—Silver plaque: "Snow, Frost, and Fog," T. G. Hibbert. Bronze plaque: "Tollers of the Deep," W. H. Barraclough. Certificate: "A Moorland Path," A. Nicholson.

Lantern Slides, Architecture.—Bronze plaque: "Doorway, St. Michel, Dijon," James R. Wigfull.

Lantern Slides (any other subject).—Silver plaque: "Stitchwort," Geo. D. Harrison. Bronze plaque: "Flowers of the Meadow," W. H. Barraclough.

The Society's challenge trophy, consisting of a silver rose-bowl, was awarded to T. G. Hibbert, for the best three prints or slides entered in three separate classes.

The exhibition remains open until to-morrow evening (Saturday). Apart from the exhibits, the attractions include animated pictures, which are shown each evening, exhibitions of lantern slides, and musical selections throughout the afternoon and evening.

FORTHCOMING EXHIBITIONS.

October 28-November 4.—Sheffield Photographic Society. Joint Hon. Secretaries, J. W. Charlesworth, 1 Joshua Road, Sheffield, and James W. Wright, 62, Vale Road, Sheffield.

November.—Edinburgh University C.C. Hon. Secretary, Harold C. Simpson, University Union, Edinburgh.

November.—Bristol and Clifton Arts and Crafts Society. Secretary, R. H. Parr, 5, Grove Buildings, Blackboy Hill, Bristol.

November, December, January.—Second American Photographic Salon. H. Snowden Ward, 6, Farringdon Avenue, London, E.C.; Wm. T. Knox, 279, Washington Street, New York City, U.S.A.

November 1-4.—Frome Mechanics' Institute Photographic Society. Hon. Secretary, Wilfred L. Watson, 14, Cheap Street, Frome.

November 1-4.—Hackney Photographic Society. Hon. Secretary, Walter Selfe, 70, Paragon Road, Hackney, N.E.

November 3.—S. Norwood Photographic Society. Hon. Secretary, George R. Beckett, 28, Carmichael Road, S. Norwood.

November 8-15.—Croydon Camera Club. Hon. Sec., W. H. Rogers 88, Woodville Road, Thornton Heath.

November 14, 15, 16.—Ipswich Camera Club. Hon. Sec., R. H. Sutton, 37, Henley Road, Ipswich.

November 16.—St. Matthew's (Bootle) Camera Club. Hon. Secretary, H. Tempest, 78, Thornton Road, Bootle, Liverpool.

November 16-18.—Burnley Camera Club. Hon. Secretary, F. Pinder, Mechanics' Institute, Burnley.

November 17.—Redhill and District Camera Club. Hon. Secretary, James Paterson, M.A., Whalley, Lynwood Road, Redhill.

November 21-25.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.

November 21-25.—Sefton Park Photographic Society. H. Cubley, 3, Langdale Road, Sefton Park.

November 23-25.—Isle of Thanet Photographic Society. Hon. Sec., L. G. Hodgson, 58, Queen Street, Ramsgate.

November 25-December 2.—Glasgow Eastern A.P.S. Hon. Secretaries, Thomas B. Kirkhope, 37, Winston Street, Parkhead, Glasgow, and John Brough, 68, Dalmarnock Street, Parkhead, Glasgow.

November 27-30.—Lancaster Photographic Society. Hon. Secretary, R. T. Simpson, 60, North Road, Lancaster.

December.—Muirkirk A.P.S. Hon. Secretary, William Barrowman, Ayr View, Muirkirk.

December 1-5.—Hove Camera Club. Hon. Secretary, A. R. Sargeant, 55, The Drive, Hove.

December 6-7.—Watford Camera Club. Hon. Secretary, E. H. Jackson, 100, High Street, Watford.

December 12.—The Scottish Photographic Federation Lantern Slide Competition. Entries to Hon. Secretary, John B. Machlachlan, Blairgowrie.

December 12-20.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 5, Pembroke Road, Portsmouth.

December-January.—Wishaw Ph. A. Hon. Secretary, Robert Telfer, 138, Glasgow Road, Wishaw.

January, 1906.—Shettleston Camera Club. Hon. Secretary, Wm. Kitson, Hawthorne Villa, Shettleston.

January, 1906.—The Dover Institute Photographic Society. Hon. Secretary, H. Plowright, 47, Maison Dieu Road, Dover.

January, 1906.—Brierley Hill Camera Club. Hon. Secretary, J. Thomas, William Street, Brierley Hill.

January 11-13, 1906.—Boston Camera Club. Hon. Secretaries, H. M. Haines and R. W. Halliday, 65, West Street, Boston.

January 13-February 3, 1906.—The Third Scottish National Salon at Dundee. Hon. Secretary, V. C. Baird, Broughty Ferry. Entries close December 30, 1905.

January 25-27, 1906.—South Essex Camera Club. Hon. Secretary, Thomas Michell, 180, Browning Road, Manor Park, E.

January 31, 1906.—Tring Camera Club. Hon. Secretary, J. Owen Raymond, Frogmore Road, Tring.

February, 1906.—Windsor Camera Club. Hon. Secretary, Thomas J. Cartland, Thames Side, Windsor.

February, 1906.—Cardiff Windsor A.P.S. Hon. Secretary, W. A. Woodward, 187, Mackintosh Place, Cardiff.

February-March, 1906.—Birmingham Photographic Society. Hon. Secretary, Lewis Lloyd, Norwich Union Chambers, Congreve Street, Birmingham.

February 3-10.—Cape Town Photographic Society International Exhibition. Entries close January 13, 1906. British exhibits will be received and forwarded by the BRITISH JOURNAL OF PHOTOGRAPHY free of charge if delivered at 24, Wellington Street, Strand, W.C., on or before December 4.

February 3-February 25, 1906.—Marseilles Fourth International Salon. M. Astruc, Sec. Gen., 11, Rue de la Grande-Armée, Marseilles.

February 6-9, 1906.—Guisbrough Fine Art and Industrial Society. Hon. Secretary, George Page, 34, Westgate, Guisbrough, Yorks.

February 13-27, 1906.—Greenock C.C. Hon. Secretary, W. D. Boyd, 2, Church Place, Greenock.

February 20-21, 1906.—Royal Albert Institute, Windsor. J. W. Gooch, Hon. Secretary.

Feb. 22-24, 1906.—Bowes Park and District. Hon. Sec., H. C. Bird, 91, Whittington Road, Bowes Park, N.

February 24—March 10, 1906.—Edinburgh Photographic Society. Hon. Secretary, J. S. McCulloch, 3A, N. St. David Street, Edinburgh.

March, 1906.—Larkhall C.C. Hon. Secretary, Robert Rodger, 26, McNeill Street, Larkhall.

March, 1906.—Leicester and Leicestershire Photographic Society. Hon. Sec., W. B. Woodland, 18, Beckingham Road, Leicester.

March, 1906.—Rugby Photographic Society. Hon. Secretary, R. N. Myers, 13, Bridget Street, Rugby.

March, 1906.—Photographic Society of Ireland. Hon. Secretary, H. V. Yeo, 194, Clonliffe Road, Drumcondra, Dublin.

March, 1906.—St. Helens Camera Club. Hon. Secretary, John Glover, 34, Ormskirk Street, St. Helens.

March 3-10, 1906.—South London Photographic Society. Hon. Sec., H. Oughton Beckett, 44, Edith Road, Peckham, S.E.

March 6-20, 1906.—Glasgow Southern P.A. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

March 7-8, 1906.—Doncaster Camera Club. Hon. Secretary, T. Haigh Connor, 39, Market Place, Doncaster.

March 12-15, 1906.—Cripplegate Photographic Society.—Secretary, Fred. Leeks, 8, Barford Street, Islington, N.

March 13-14, 1906.—G.E.R. Mechanics' Institute (Stratford). Hon. Secretary, A. Woolford, 16, Grove Green Road, Leytonstone, E.

March 14-17, 1906.—Nottingham Camera Club. Hon. Secretary, S. W. Barlow Yines, Market Chambers, South Parade, Nottingham.

March 19-24, 1906.—Sunderland Photographic Association. Hon. Sec., William E. Kieffer, Stirling Street, Sunderland.

April, 1906.—Barrhead Amateur Art Club. Hon. Secretary, R. Murray, 146, Main Street, Barrhead.

April 1, 1906.—Coatbridge Co.-Op. C.C. Hon. Secretary, James Robb, 6, Windsor Terrace, Blenheim, Coatbridge.

April 20-21, 1906.—Watford Photographic Society. Hon. Secretary, C. J. Trevarthen, Ashcroft, Bushey Hall Road, Watford.

May, 1906.—Warrington Photographic Society. Hon. Secretary, A. C. Smithson, 13, Chester Road, Warrington.

FORTHCOMING COMPETITIONS.

November 30.—Royal Photographic Society "Affiliation" Print Competition. Particulars from the Secretary, 66, Russell Square, W.C.

December 30.—Royal Photographic Society "Affiliation" Lecture Competition: (a) Illustrated lecture descriptive of a tour (b) Illustrated technical lecture. Particulars from the Secretary R.P.S., 66, Russell Square, London, W.C.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for Patents were made between October 16 to 21:—

TRIPODS.—No. 20,931. Improvements in tripods for photographic cameras. William Butler, 139, Dale Street, Liverpool.

LENS.—No. 21,164. A new or improved lens for photographic objectives. Stephen Drummond Chalmers, 8, Quality Court, Chancery Lane, London, W.C.

POSTCARDS.—No. 21,205. A method of adapting stereoscopic and lantern transparencies for use as postcards. Courteney Spencer Jones, Montsorel, Woodford Green, Essex.

DEVELOPING APPARATUS.—No. 21,412. A combination dark-slide plate, carrier, and daylight developer for plates. George Henderson, 4, Newby Terrace, Stockton-on-Tees.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

COATED PAPERS FOR EMULSIONS.—No. 17,303, 1905. The claim is for the application to a raw paper (of wood pulp or other cheap material) of a fibrous protective coating of thin paper, fabric, etc., which is laid on the raw paper by means of an adhesive, etc. The fibrous layer is stated to prevent the penetration of the emulsion better than other applications, such as that of baryta, but it is also stated that baryta may be applied in addition to the fibrous coating. Ignaz Hoffmüller, 11, Schenkelsstrasse, Düren, Rhine Province, Germany.

COLOUR-SENSITIVE EMULSIONS.—No. 24,290, 1904. The claim appears to be for an emulsion containing dyes such as ethyl red, eosine, erythrosine, etc., which increase the sensitiveness of the silver haloid. Gustav Koppmann, 29, Hohe Bleichen, Hamburg, Germany.

THREE-COLOUR PHOTOGRAPHY.—No. 21,210, 1904. The patent relates to the making of trichromes on glass or line colour screens so as to (1) avoid staining of one image by another; (2) produce screens of finer ruling; (3) produce a screen firmly built together with absence of air-bubbles, blisters, etc.; and (4) make the screen so that the outer surfaces of the coloured portions are in the same plane or at one level. The glass is coated with a substratum such as water-glass, and a layer of coloured gelatine applied either in the coloured state or uncoloured for subsequent dyeing. The coloured gelatine film prepared in either way is sensitised in a bichromate bath, printed, and developed. For the second and third monochromes it is most important that the colour be inserted into the film before development, but for the first it will answer as well whether put in before sensitising and printing, or before or after development. It is preferable, however, to colour the gelatine from the start, and to print from the negative or line-screen. In the latter case, the engraved or ruled side of a half-tone screen, having a patterned area containing white or transparent spaces one-half as wide as the opaque spaces, is laid against the sensitised side of the film, and the printing done through the white areas. In either case, the image lies in an area or areas of the coloured gelatine film determined by the nature of the stopping-out medium, whether a photographic negative or a line-screen. Such first colour areas are indicated by the reference c^1 . The next step is the

preparation of the plate for the reception of a second gelatine film. This can be done in a variety of ways, the method of preparation depending, firstly, on the nature of the intermediate or protective film employed, and secondly, on the method employed in putting on the gelatine film out of which is to be formed the second image. With celluloid used as an intermediate or protecting film, the successive operations are as follows:—The first image being finished, a thin film of colourless gelatine, c^1 Fig. 1, is washed over the plate and allowed to dry. Then a solution of celluloid, so prepared that it will adhere to the underlying image during the subsequent operations, is flowed over this and allowed to dry: for instance, by adding glacial acetic acid in quantity sufficient to slightly dissolve the underlying film of soluble gelatine and thus weld the two surfaces together. After dyeing the whole is insolubilised, converting the films into an inseparable mass, i^1 . The plate, now ready for the film out of which is to be formed the second image, is treated as if it were a new plate, that is coated with soluble glass, then a thin wash of gelatine over which the coloured gelatine film c^2 is squeegeed; this is sensitised, printed, and

Fig. 1.

Fig. 2.

developed. Then a colourless film of gelatine is flowed over the plate, and when dry is coated with the celluloid solution and allowed to dry. This is hardened or insolubilised, and forms the film i^2 . The image c^3 is then formed, the series of operations being the same as for c^2 . The resulting polychrome photograph may be mounted for viewing by either transmitted or reflected light, and it may be transferred on paper if the glass support G has been suitably prepared for that purpose. When using this process in the manufacture of parti-coloured screens, the patterned black and white screen above mentioned is used for stopping out the light at each printing operation, the areas of the second and later coloured gelatine films exposed thereby and printed there-through being at one side of and in contact edge to edge with the similar areas of the previously printed film or films, so that, in the finished screen, the light-shifting media are juxtaposed without perceptible intervals between them. In using the process for manufacturing trichromatic views or taking screens, the first step may be as above described, and the preparation of the glass for the second and the third coloured gelatine films, their transfer, sensitising, and development may also be as above set forth in connection with the manufacture of a polychrome photograph. In printing the image or areas, however, the black and white line screen, for the second and third colours, is laid against the sensitised film so that its opaque areas will cover the image or areas previously printed, and so as to bring the areas of the second image or colour edge to edge against the first image or areas without overlapping.

clear spaces, and so as to bring the third set of coloured areas in between and against both the first and second sets of coloured areas without overlapping and without leaving clear spaces. When the areas, as linear strips, of the screen for use in colour photography, are to be very small and fine, it is important that their outer faces shall lie in one plane, as, otherwise, the screen will not be satisfactory on account of the divergence of the light rays, especially when using wide-angle lenses. Fig. 2 illustrates the formation of a screen by this process when it is desired to have the coloured areas in one plane or with their outer faces in such a plane. The operation of making such screen may be described as follows, viz.:—The transparent support G, as a glass plate, is provided with a suitable substratum s^1 , as water glass. Then the first colour is put on in the following way: First the substratum is coated with a colourless film of soluble gelatine and of the required thickness; on which a coloured gelatine film is transferred cold and its flexible support removed. Next, the gelatine film is sensitised, printed behind a black and white screen as above set forth, and developed, leaving separated areas c^1 on the glass or support. The colourless film forms blocks b^1 between the areas c^1 and the substratum s^1 after the development, etc., as shown in Fig. 2. Then the glass is prepared for the second colour as follows:—The areas c^1 and blocks may be impermeabilised or fixed against absorption of colour, and, if necessary to varnish, a colourless film of soluble gelatine is washed over the glass and areas c^1 , after which a varnish, or a protective coating i^1 , which will adhere to the gelatine during subsequent operations, is put on, and the whole rendered insoluble. Next, a film of water glass is put on, over which a layer or film of colourless soluble gelatine is put, after which the second coloured gelatine film is put on cold, and its flexible support removed. Then it is sensitised, printed behind the black and white screen as described above, and developed, leaving areas c^2 on the glass support with blocks b^2 thinner than blocks b^1 , said blocks b^2 being formed from the last-mentioned film of colourless soluble gelatine. A new isolating and binding film i^2 is next prepared, and a third colour is put on, printed, etc., and developed in like manner, leaving areas c^3 having blocks b^3 thinner than b^2 and b^1 . Or the blocks b^3 may be omitted if necessary to secure flatness of surface. By this process have been made tricolour screens having over 500 lines to the inch, free from blisters, hair lines, and overlapping of colours, and with their outer surfaces in substantially the same plane. The aggregate thickness* of the screens, exclusive of the glass or other support, is very small, being much less than the thousandth part of an inch. The process shown in Fig. 2 need only be used when the lines are very fine, but for screens of moderate fineness the process as shown in Fig. 1 will be found to answer all requirements. Among the difficulties encountered in the manufacture of such polychrome screens, both taking and viewing, is that of having the different lines of the respective intensities of colour required. It thus becomes necessary, when the negative is made, to use a supplementary monochrome screen. In the case of positives it is also necessary to use a supplementary screen and to dip the positive itself in a suitable dye-bath. To render the use of such monochrome screens unnecessary, the finished screens, both taking and viewing, are coated with a thin gelatinous solution, and this film then dyed in a suitable bath. One is thus enabled to obtain absolutely grey viewing screens, and can also regulate and correct the relative intensities of the colours of the taking screens. Charles Louis Adrien Brasseur, No. 10, East 15th Street, New York, U.S.A.

Bla.

The following complete specifications are open to public inspection before acceptance under the Patents Act, 1901:—

CATATYPES.—No. 20,372, 1905. Reproduction of pictures with the aid of catalysis. Neue Photographische Gesellschaft.

APPARATUS.—No. 20,570. Photographic apparatus. Anderson.

CURVE-DRAWING.—No. 20,579. Photographic curve-drawing apparatus. Siemens and Halske.

New Material.

Merck's crystal pyro (E. Merck, 16, Jermyn Street, London, E.C.) is now manufactured in a somewhat coarser form than hitherto. The sample submitted to us we find to dissolve freely in water to a bright solution, and a brief experience of it in developing some plates leaves us in no doubt of the high degree of purity to which the Merck pyro, cryst. or re-sublimed, has made a legitimate claim in the past. Personally our preference is for the crystal form, and the maker's present departure renders the developing agent a shade more convenient to handle.

We are indebted to the author, William Cotton, M.D., for a reprint of a paper on "Twin X-ray Representation and the Reflecting Stereoscope" from the "Bristol Medico-chirurgical Journal." It describes the application of a Wheatstone reflecting stereoscope to the production of radiographs of fractured limbs. A bibliography of X-ray stereoscopy is appended.

A PAMPHLET—"Colour Photography in a Nutshell"—reaches us from the author, the Rev. Jevon James Muschamp Perry, for whom apparently it is published, at the modest price of 3d., from the "Guardian" office, Alnwick. It deals very simply, and evidently as the result of experience, with the making of transparencies by the Sanger-Shepherd process.

SIR BENJAMIN STONE'S PICTURES.—As announced in these columns some time ago, Messrs. Cassell and Co. are issuing in fortnightly parts a series of reproductions from the collection of "record" photographs made by Sir Benjamin Stone, M.P., of national life and history. The first part of this series is to hand, and proves to be a remarkably well-produced publication, containing sixteen full-page reproductions (whole-plate size) on art paper of photographs of festivals, ceremonies, and customs. Interpolated with the plates is descriptive letterpress, and the whole, when complete in several volumes, will form a unique addition to the library of every Englishman interested in the manners and customs of his own country. Sir Benjamin Stone's untiring efforts in survey and record work have raised him almost to the position of a national institution, and the great charm of many of his pictures is that facilities have been afforded him for securing them that would have been denied to nearly every other photographer. The commonplace and the unimportant have been avoided, and although Sir Benjamin would be the very last to claim anything for his photographs than that they are absolutely "unfaked" records of events, etc., artistic merit is not lacking in some of them. Messrs. Cassell are advertising this publication extensively, and it is well worth the 7d. charged for each part.

On Thursday, October 26, the L. and P.P.A. Henderson award was unanimously voted to Mr. A. J. Bull, of the L.C.C. School, Bolt Court, for his paper on "Orthochromatic Photography," read before the Association on February 23, 1905. This paper was given in full in the B.J. for March 3.

New Apparatus, &c.

The Nernst High-Power Lamp. Made by Robert W. Paul, 68, High Holborn, London, W.C.

The Nernst lamp, which has steadily grown in favour for enlarging and projection purposes, is now issued in a new pattern by Mr. Robert W. Paul. Its features are first a high power, ample for large commercial enlarging, and secondly adjustability for various current voltages. Moreover it is made in a shortened form for use in lanterns of the smallest dimensions. The lamp takes a current of three amperes, and by using one or more of a set of filaments fitted by small brackets to the front of the lamp can be used at high or low power.

In circuit with each filament, and contained in the body of the lamp, is a resistance of iron wire enclosed in a glass bulb fitted into a bayonet socket. These resistances are used to steady the current, and also to protect the filaments by acting as fuses in case of excess of pressure.

The lamp is started by heating the filaments with a spirit lamp until red hot, and the lamp is provided with a pivotal movement by which the spirit flame can be conveniently applied to the battery of filaments. The result is an intensely luminous area, equal in power to a good blow-through jet, and of a brilliant white colour.

The figure shows the convenient way the lamp is mounted, half in and half out of a small lantern. The system is just as conveniently applied to small projection lanterns, which can thus be used to efficiently illuminate discs up to 10 ft. in diameter. Our own conclusion from seeing the lamp in use is that the enlarger and amateur lanternist will find it difficult to obtain a light more suited to his purposes. The price of the ordinary pattern, complete with resistances, one burner, three filaments, and flexible connection is £2 10s., of the shortened pattern seen in figure, £3 10s.

News and Notes.

A PAMPHLET setting forth the activities of the Scottish Photographic Federation for the session 1905-6 is at once an outward and visible sign of the many instances in which Scotsmen are bent on being in the vanguard of modern photography. And the Scotsman in the Federation seems equally determined on taking every (Federated) individual along with him, if it can be done by lecture, demonstration, or portfolio.

BRITISH ASTRONOMICAL ASSOCIATION.—The annual general meeting of this association was held at Sion College, Victoria Embankment, E.C., on Wednesday of last week. The President (Mr. C. D. Crommelin), in his address, commented on the great advance in Martian photography that had been obtained at the Lowell Ob-

servatory. The results, he said, confirmed the objective reality of the canals on Mars. They would also serve to improve the maps of the planets, since the outlines of the so-called oceans were plainly shown and could be accurately measured. As a result of a ballot taken, the following officers were declared elected for the ensuing session:—President, Mr. A. C. D. Crommelin; vice-presidents, Messrs. E. W. Maunder, S. A. Saunder, W. H. Wesley, and C. T. Whitmill; treasurer, Mr. W. H. Maw; secretaries, Messrs. J. G. Petrie and J. A. Hardcastle; librarian, Mr. F. W. Levander; other members of the council, Mrs. E. W. Maunder, Dr. Smart, and Messrs. G. F. Chambers, Tyson Crawford, W. Heath, H. P. Hollis, W. T. Lynn, G. J. Newbegin, T. Thorp, and A. S. Williams.

In the "Court Circular" of the "Times" is the announcement that her Majesty the Queen, attended by the Countess of Antrim, honoured Mr. Edward and Miss Alice Hughes with a visit at their studios in Gower Street on Thursday last.

STELLAR Photography.—During the recent proceedings of the British Association meeting at Johannesburg, Dr. A. A. Rambaut, of the Radcliffe Observatory, Oxford, described an instrument for measuring stellar photographic plates on which the latent image of a réseau has been impressed and developed with the star images. Such a réseau the author describes as a "black" réseau, and the side of the square, which is 5 mm., corresponds to an angle of 150" in the Radcliffe telescope. By an ingenious arrangement of lenses the image of a small réseau, ruled on a silvered glass plate, is projected on the "black" réseau, and since the lines appear bright is denoted as a "white" réseau. This white réseau contains sixteen lines in each direction—i.e., mutually at right angles, so that the outer lines form a square which just fills one of the squares of the black réseau, from which it will be seen that the white réseau interval is equal to 10". The micrometer screw carrying the silvered glass plate on which the white réseau is ruled has a pitch of 10", and the heads being divided into 100 parts and read by estimation to tenths, a unit in the last figure is equivalent to 0".01. When the plate to be measured is inserted in the machine the preliminary adjustments of focussing, bringing the lines of the black réseau parallel to the slides and those of the two réseaux into sensible parallelism, can be effected in two or three minutes by means of the adjusting screws provided for that purpose. These adjustments having been satisfactorily completed, the observations for measuring the position of a star image with regard to the réseau square in which it lies are as follows: The black réseau is first set so as to coincide approximately with the white. Using the micrometer screws, three corners of the white réseau are then brought in succession to coincide exactly with the corresponding corners of the black réseau. As the white lines are considerably thinner than the black, and appear neat and sharp when projected on the somewhat softer black lines, this is an observation which can be made with great delicacy. The probable error of a single setting was found to be 0".02.

THE Hon. Secretary of the Southampton Camera Club asks us to remind our readers that the last day for entries for the club's fifth annual exhibition is Saturday, November 11. Entry forms and full particulars can be obtained from S. G. Kimber, Oakdene, Highfield, Southampton.

WISHAW PHOTOGRAPHIC ASSOCIATION.—This Society holds its annual exhibition on December 29, 1905—January 4, 1906. There are six open classes, viz., Portraiture, Landscape or Seascape, Architecture, Flower, Fruit, or Still Life, Lantern Slides, Any Subject (confined to exhibitors who have never gained an award in open exhibitions). The judge is Arch. Cochrane, of Barrhead. The awards offered are one solid bronze plaque, 4½ in. by 2½ in., and two bronze medals in each class. Closing date for entries, December 18, 1905. Receiving dates for pictures, December 22 and 23, 1905. Entry forms may now be had from the hon. secretary, R. Telfer, 138, Glasgow Road, Wishaw, N.B.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Nov.	Name of Society.	Subject.
3.....	Colne Camera Club.....	"Gum-bichromate." Demonstrated. Mr. W. Baldwin.

9.....	Balham Camera Club	"Printing and Finishing P.O.P." Mr. C. W. Cox.

HARROGATE CAMERA CLUB.—"Retouching" was the subject of a demonstration given by Mr. John Way, of Pudsey, on Thursday evening of last week, in connection with the Harrogate Camera Club, in the lecture room of the Builders' Exchange, Harrogate. At the outset, Mr. Way particularly asked his hearers that, if they were fortunate in learning anything from his demonstration, and should ultimately perfect themselves in the art of retouching, he earnestly hoped they would use their knowledge fairly and not in any way to injure the professional by doing work for others

at cutting prices. The outfit was first described, and proved to be very simple and inexpensive. The desk was one of the demonstrator's own construction, and he claimed it to be the simplest and most efficient he had seen. It was sufficiently large to take a 15 by 12 negative, and instead of the usual panel arrangements for taking different size negatives, an aperture about 3 in. square was cut in the centre. A piece of grooved wood, to one end of which a piece of strong elastic was attached, and to the other end a button, served to hold the negative in position. By passing the elastic behind the desk and looping on to the button, this was held firmly, and by moving up or down, any part of the negative was brought over the aperture, through which the light was passing from the back. To further reduce the strain on the eyes, pieces of opaque paper, with small openings, were placed over the negative, thus reducing the light area to that part only which the operator desires to retouch. Seated at the desk, Mr. Way gave practical lessons to each one in turn, and members were afterwards invited to try their hand. The lecturer particularly impressed on his hearers that the work of retouching could only be acquired by constant practice, and that they were not to be discouraged by first failures.

CROYDON CAMERA CLUB.—Mr. J. W. Eadie, vice-president of the Scottish Photographic Convention, on the 25th ult., gave a practical demonstration on bromide paper and enlarging, having special reference to the well-known products of Messrs. Kodak, Limited.

CROYDON NATURAL HISTORY AND SCIENTIFIC SOCIETY.—At a meeting of the photographic section of this society, held on Wednesday evening, the 25th ult., Dr. Hobson gave an address on "How to do it and how not to do it," illustrated by a large number of lantern slides. The composition of the pictures shown by the slides was criticised by the members present, and Mr. Leonard Skeats, who was amongst the visitors, pointed out the good features and the defects of the pictures from the point of view of an artist who is not a photographer. It is proposed at the November meeting to submit a number of finished prints contributed by members for open criticism in the same way.

THE BRISTOL PHOTOGRAPHIC CLUB.—This club held its annual general meeting on Tuesday evening, October 24, at 5, St. James's Square. Satisfactory reports were submitted by the secretary and the treasurer. It was gratifying to learn that the membership had more than doubled during the year. The following were elected to office:—President—John Fisher, Esq., Hon. A.R.C.A. Vice-presidents—Mr. T. W. Brown and Mr. H. R. Harford. Council—Messrs. F. H. Stevens, M. B. Fowler, R. W. Coates, Fred Little, J. S. Guthrie, and G. Easonsmith. Hon. Folio Secretary—Mr. H. R. Harford. Hon. Treasurer—Mr. E. Beaven. Hon. Secretary—Mr. W. W. Smith, 62, Sefton Park Road, Ashley Down, Bristol.

CONSETT AND DISTRICT PHOTOGRAPHIC SOCIETY.—The annual meeting of this society was held last week in Luton House, Middle Street, Consett. The report stated that the past year's proceedings, fully justified them in taking Luton House, that venture having been entirely successful. The financial statement showed that they had reduced the debit balance from £16 18s. 8d. to £4 13s. 10d. The officers were elected as follows:—President—Captain Petherick. Vice-presidents—Mr. H. Palmer, Mr. R. G. Barclay, J.P., Mr. T. L. Gledstone, Mr. William Davison, Mr. E. G. Kirkhouse, Mr. T. Duckworth, Mr. William Nicholson, Mr. E. Cellan Jones, and Mr. E. Taylor. Secretary—Mr. P. E. Surtees. Assistant Secretary—Mr. W. E. Massey. Treasurer—Mr. P. H. Sanderson, York City and County Bank, Consett. Auditor—Mr. W. E. Urwin. Committee—Mr. W. Bird, Mr. J. H. Courtney, Mr. William Smith, Mr. Jesse Hall, Mr. U. Rollinson, and Mr. R. Gardner.

NORTH LONDON PHOTOGRAPHIC SOCIETY.—A society for Highbury, Finsbury Park, and adjacent districts has been formed with the above title. It is expected that the society will commence work on the first or second Thursday in January, and a course of lectures and demonstrations will be arranged. The annual subscription has been fixed at 5s., no entrance fee being payable by gentlemen joining before the end of this year. Forty-two gentlemen have already become members. The first members' meeting will be held at Highbury Vale Mission Hall, Myrtle Street, Blackstock Road, N., on Thursday, November 16, at 8 p.m., when the officers and committee for the ensuing year will be elected. Any gentleman desirous of becoming a member or wishing for further information is asked to communicate with Mr. Charles Roberts, 33, Riversdale Road, N., hon. secretary (pro tem.), who will also be glad to hear from trade and other lecturers with a view to their being included in the first season's programme.

CATALOGUES AND TRADE NOTICES.

EXCELLENT photographic reproductions of the pictures of the late T. Sydney Cooper, R.A., are being placed on the market by Mr. Edmond Wallis, studio accessory maker, of Dunton Green, Kent. These photographs, which are first-class specimens of copying work, are supplied to photographers and the trade, and should prove a good side line during the winter months. There are sixteen in the series, and, depicting, as they do, some of the masterpieces of the famous animal painter, are likely to be popular, especially when suitably framed, as presents for Christmas and the New Year. A reference to our advertisement pages will give further particulars concerning them, and application should be made for terms.

"FALLOWFIELD'S Photographic Annual for 1906" reaches our table as a ponderous volume of 1,220 pages—a veritable encyclopædia of photographic apparatus and materials. It is a volume which in the past we have never allowed far from our table, and the present issue, larger but just as well arranged as its forty-three predecessors, is absolutely the most comprehensive catalogue a photographer (professional or amateur), can possess. An hour spent in perusing its pages will probably persuade the most satisfied worker that in some particular or other he might be better provided. Big as it is, Mr. Fallowfield's list is easy of consultation, and in its universal use of illustrations—there are 2,122 of them altogether—the finest means of illustrating, of enabling the purchaser at a distance to see what he is buying. The "Annual" costs 1s. 6d. post free.

Two seasonable price-lists are among the new issues of Messrs. Houghtons Limited:—No. 1 of Christmas greeting cards, and forcibly illustrated by half-tone blocks. The character of the variety of cards thus obtains adequate representation, and the list is quite an incentive to purchase. List No. 2 is of enlargers and enlarging accessories. Both are the sort of catalogue for a dealer to place in his clients' hands.

A new list of Boardman's arc lamps, 10, Southwark Bridge Road, London, S.E., reaches us, with a convincing list of photographers now using them.

THE "Foldscope" is the name given to a new and convenient series of folding stereoscopes recently introduced by Kodak, Ltd., 57-61, Clerkenwell Road, London, E.C. Containing all the necessary features of a good stereoscope, these instruments are made to adjust and fold into a remarkably small compass. They are well made in metal, the bright parts being electro-plated. In view of the revival of interest in stereoscopic photography, the "Foldscopes" should prove very popular. They are inexpensive.

Commercial & Legal Intelligence

"PHOTOGRAPHIC INDUSTRIES."—Resolutions for winding up voluntarily have been passed and confirmed, and Mr. W. Leal, 12, King William Street, E.C., appointed liquidator. The company is in liquidation for the purpose of returning the subscribed capital to the shareholders.

AN Alien's Alternative.—A Pole named Dosteel, was sued on a judgment summons, in Wandsworth County Court, on Tuesday last, by Messrs. Tudor, Hora, and Co., photographic chemists, of York Road, S.W., for £14 19s. 11d., for goods supplied at cost price and "money lent to pay the brokers out." The plaintiff's representative stated that about three months since, the defendant recovered £125 damages and costs against his landlord in the High Court. The defendant: I am doing nothing at present. His Honour: What nationality are you. The defendant: A Pole. I offer 5s. a month. His Honour: That is ridiculous. Two pounds a month, or committal in default. If you do not like it you can go back to Poland.

DOUBLED His Wages by Fraud.—At Worcester, on Thursday, Charles Arthur Williams, 27, photographer's assistant, of Bransford Road, was charged with a series of embezzlements from his employer, Horace Henry Dudley, of West Bromwich, for whom he acted as manager of the Worcester branch at Broad Street, Worcester. Mr. W. W. A. Tree, who prosecuted, said the prisoner had by systematic fraud on his employer exactly doubled his wages. There were three classes of fraud. In the one case the prisoner had received moneys from customers for which he had not accounted, representing that the people had had free sittings; in other cases he accounted for only a portion of the moneys received, and he had also made charges for cleaning which was done by the boy employed by the prosecutor. Defendant pleaded guilty to all the charges with the exception of one in respect of 4s. Mr. E. C. Harrison, for the defence, pointed out that the defendant had built up a good business, and had fallen a victim to the temptation offered by a coupon system. Defendant offered to make restitution to the amount of £25. The Bench remarked upon the deliberate character of the fraud, and sentenced prisoner to three months' hard labour for the embezzlement. A further charge of fraud was withdrawn.

A. W. PENROSE AND Co., LIMITED.—This company has been registered with a capital of £40,000, in £1 shares (10,000 6 per cent. preference). Object: To acquire the business carried on by A. W. Penrose and Co., at 109, Farringdon Road, E.C., to adopt an agreement with A. W. Penrose, and to carry on the business of manufacturers of and dealers in all machinery, apparatus, material, and appliances used in connection with photography, etching, engraving, drawing, painting, printing, or other graphic arts, manufacturers of electric cranes and hoists, makers of printing machine motors and gears, electrical and general engineers, etc. No initial public issue. The first directors (to number not less than three nor more than five) are A. W. Penrose, W. Gamble, and D. Munro. A. W. Penrose is governing director, and may retain office while holding 5,000 shares, with power to appoint other directors. D. Munro is nominated by the Law Guarantee and Trust Society, Limited. Qualification (except above-named directors and any other director nominated by the said society), £100. Remuneration of A. W. Penrose, £600 per annum. So long as the guarantee of debentures by the Law Guarantee and Trust Society, Limited, remains in force, the total remuneration of directors (including governing director) shall not, without the consent of the said society, exceed £1,000 per annum. Registered office, 109, Farringdon Road, E.C.

CHRISTMAS CARDS.

To the Editors.

Gentlemen,—In a leaderette in the last issue of the JOURNAL, under the heading "Preparing for Winter Business," you recommend photographers to make original designs for their Christmas post-card borders, photograph them, and transfer them to the cards by double printing.

I have practised the method for some years for private Christmas cards, and as the process is so simple, requiring no skill in drawing, and requires less time in printing than an ordinary vignette, I agree with you in expressing surprise that the profession have not taken it up, as it affords such scope for original idea in design.

In the "Almanac" for 1901 (p. 713) I gave full details of a process for Christmas cards, and to adapt it to the present postcards the design board should be 21 x 33 inches, which on a half-plate will reduce to postcard size—viz., $3\frac{1}{2}$ x $5\frac{1}{2}$ in.

The advantage of my method is that holly, flowers, fruit, shells, etc., etc., as taste and fancy many dictate, may be used for the border design—the camera does the rest.

I enclose a specimen print showing one design of border.—Yours truly,
169, Commercial Street, Lerwick.

JOHN LEISK.

THE TITLE OF A PICTURE.

To the Editors

Gentlemen,—Referring to my previous letter which you published, I find, in further correspondence with the Secretary of the Royal Photographic Society that the mistake made in the title of my pictures is in no way due to any error on his part, but to the fact of my frame-maker reversing the titles on the two pictures. Will you kindly give this the same publicity as my first letter and oblige?—Yours faithfully,

EDWIN H. HAZELL.

Linden Road Studios, Clevedon,

October 26, 1905.

THE PERMANENCY OF MATT COLLODION PAPER.

To the Editors.

Gentlemen,—I was much interested by Mr. Busbridge's letter in your current issue dealing with the permanency of pictures on matt collodion paper, for only the other day, in looking over some prints made about three months ago on the matt collodion paper of a well-known firm, I was surprised to find that they were all afflicted with what, in the diction of Mr. Pepys, might fairly be called "the spotted fever." I submitted some of these faded prints to the makers of the paper, and received from them a very courteous letter, in which probable reasons were assigned for my misfortunes. But the only reason adduced that I think could possibly apply to my case was to the effect that the blotting paper, used for the purpose of lightly mopping the prints after washing, was contaminated in some way. At first I was inclined to accept this suggestion as the true cause of my failures, but the story of Mr. Busbridge's experience is unsettling, suggesting, as it does, the possibility of an inherent in-

stability of the image on the class of papers concerned, quite apart from all misadventures and mischances in their manipulation. I must, however, confess that my experience of matt collodion papers is strictly limited, being, in fact, confined to the unfortunate instance I have described.—Yours, etc..

DOUGLAS CARNEGIE.

October 28, 1905.

To the Editors.

Gentlemen,—In reply to your request in "B.J." October 27, as I have had a large and varied experience with this class of paper, may I venture to state that I have never had cause to complain of the permanency of this process if properly worked.

I have experienced great difficulty at times, the prints being, as your correspondent states, covered with spots and patches, much lighter in colour than the other parts of the picture, but in every case, I have found it due to carelessness on the part of the printers or impure mounts and mounting papers. I have before me a set of prints in Matt C.C. double-toned. These prints were made about four years ago, they have travelled over Great Britain many times, and been exposed to all sorts of rough usage, yet they are as rich and pure in colour as the day they were toned and fixed.

With the double-toned prints the image seems particularly soluble in hyposulphite of soda, and it is this peculiarity that is the cause of most of the faded prints.

I have repeatedly found that the blotters used in mounting are contaminated in some way, sometimes even with particles of hypo. These are imparted to the damp collodion prints when mounting, and of course fading ensues. Minute crystals of hypo in the form of dust might settle on the print while damp with again the same result.

It is not to be supposed that these conditions would obtain with an experienced worker, but, owing to cheapness, mere apprentice hands, mostly girls, are left to do the printing and toning. They know nothing whatever of photography, and, necessarily, failure results. I have even known the mounting blotters to be placed within six inches of a cask of hypo, and have actually seen the hypo crystals dropped upon them by workers of this class. Why wonder any longer at the fading of prints?

I am writing from personal experience, and I have produced identical stains myself by pressing contaminated blotters into contact with damp prints. Yet again, I repeat there is no real cause for fading.

If new toning and fixing solutions are used, the prints are well washed, and clean workers and blotting paper is the rule, and not the exception, as is often now the case in the photographic atelier, then we shall hear less of fading prints and printers' troubles. Still, there will always be the dissatisfied worker, but perhaps, to quote the words of one of them, the only complaint will be:—

"Oh, don't the days seem limp and long,

When all goes right and nothing wrong."

Apologising for the space I have taken, I beg to remain yours most sincerely,

BERTRAM T. HEWSON.

Elham, Canterbury, October 27, 1905.

THE RESTORATION OF DAGUERREOTYPES.

To the Editors.

Gentlemen,—In reference to your answer last week to a correspondent on the subject of cleaning Daguerreotypes, we believe our Mr. W. Kent is almost the last living Daguerreotypist, having opened his first studio in the year 1848 in New York. He has had numbers of old Daguerreotypes through his hands for restoration.

The greatest risk in treating them arises from the "gilding" or "non-gilding" at the time they were taken. An error of judgment in this respect involves the total destruction of the image, if treated

in the manner to which you refer in your reply to your correspondent.

—We are Gentlemen, yours truly,
104, Terminus Road, Eastbourne.

October 28, 1905.

WHENCE COMES THE WORD "PHOTOGRAPH"?

To the Editors.

Gentlemen,—Although the history of photography as an art has been very carefully investigated and fully written, I have nowhere seen any statement of the invention or introduction of the name, or of the cognate words photograph and photographic. Histories which tell minutely when and by whom such names as heliotype, daguerrotype, calotype, photogenic picture, etc., were invented, have apparently nothing to say about the first inventor of "photograph." We are anxious to give the history of these words in the Oxford "New English Dictionary." Will lovers of photography kindly help in tracing them to their first appearance? At present the earliest occurrence known to us is in the paper read to the Royal Society by Sir John Herschell on March 14, 1839, entitled "Note on the Art of Photography, or the Application of the Chemical Rays of Light to the Purpose of Pictorial Representation." In the paper as printed in the proceedings, he uses photography, photograph, and photographic, as freely and naturally as any one uses them to-day; the inference from which would be that they were then in everyday use, or at least well known to his audience. But, strange to say, we have not succeeded in finding them anywhere earlier. They were not used by Niépce, Daguerre, or Fox Talbot. The latter read a paper to the Royal Society on his own discoveries just six weeks before Herschell, in which he never uses the terms; his name for photography was photogenic drawing; his photographs also were "photogenic drawings." French friends have also failed in tracing the word photographié in French before 1839. Whence, then, did Herschell get the word? He does not claim it as his own, explain it, or comment upon it in his paper (so far as this is reported in the proceedings), as he does, for example, in introducing the terms positive and negative, of which, in their photographic application, he was the author. Can it be that, in the experiments that he had made for several years, he had invented the name photography for his own private use, and became so familiar with it, as to use it in his paper without thinking of explaining it, or can any source be discovered whence he obtained it? It does not seem right that the origin of "photography," or light-drawing should itself remain in darkness, and that we should have to say of a word, which apparently arose within the lifetime of many still with us, and has been for years on everybody's lips, that its origin is unknown? Its analysis and Greek derivation are, of course, transparent enough; but what we want to know is its history—who made it, and when?

Oxford, October 28, 1905.

J. A. H. MURRAY.

[We refer to Dr. Murray's letter under "Ex Cathedra."—*Eds. B.J.P.*]

As Eastman Function.—On October 7 took place the opening of Mr. George Eastman's magnificent residence at 350, East Avenue, Rochester, and to the house-warming Mr. Eastman invited some 100 guests connected with the various Kodak enterprises. The occasion was evidently one that will long be remembered by the participants.

Der Verein zur Förderung der Photographie, the leading photographic society of Berlin, are projecting an international exhibition, to be held during July, August, and September next year in one of the large public galleries of Berlin. The exhibition is to embrace scientific, technical, as well as pictorial photography, and it will also include photographic manufactures.

Answers to Correspondents.

- *.* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- *.* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- *.* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- *.* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- W. E. James, 8, Parchment Street, Winchester, Hants. *Photograph of the South Side of Winchester Cathedral on Props.*
- W. E. Welchman, The Studio, Exchange Street, Retford, Notts. *Photograph of West Bridge, near Retford. Photograph of Winney Moor, Retford. Photograph of Ordsall, near Retford (from Bridge).*
- H. Osguthorpe, 18, King Street, Spennymoor, County Durham. *Photograph of Tom Lancaster, of Spennymoor (Buxer).*
- E. Austin, 54, Union Street, Wednesbury, Stafford. *Photograph of Passive Resistors' Sale, Wednesbury.*

COLONIES.—1. Sharland's "New Zealand Photographer," Lorne Street, Auckland, N.Z. 2. "Australian Photographic Journal," 386, George Street, Sydney; "Australia and Australian Photographic Review," 375, George Street, Sydney. 3. "St. Louis and Canadian Photographer," 3,210 Locust Street, St. Louis, Mo, U.S.A. There are no journals in the other places you name.

J. G.—The paper is an ordinary collodio P.O.P., such as you will see advertised by several firms in our pages. It is toned with gold or platinum, or can be purchased of the self-toning variety. If you consult the formulæ section of the ALMANAC you will see how to set to work.

TONING FORMULA. Should esteem it a great favour if you would tell me of good toning bath for Paget P.O.P.; one you can recommend for warm tones, such as red and warm-brown, etc. Also, what should the temperature of the baths be.—*Pro.*

You will find full information in the booklet on P.O.P. issued by the Paget Company. Surely they are the best people to advise you.

PREVENTING SALE.—We should be pleased if you would let us know whether we can stop a non-copyright photograph from being sold by others.—*D. B. M.*

No; certainly you cannot. If the copyright is vested in you, you can register it; then you can prevent further sales of the picture.

CARBON TRANSPARENCIES FOR THE STEREOSCOPE.—Will you be kind enough to tell me how to transpose the pictures in making stereo transparencies by the carbon process? It seems a little puzzling. Must the negatives be cut?—*A. F. P.*

By far the simplest method is to cut the negatives and transpose them as regards right and left. Failing that, mark the negatives so as to just include the subject desired. Then cut the tissue so that the two pieces, when together, are a little smaller than the glass they are to be developed upon. Print the pieces, of course marking them so as to know

which is right and which is left, and it is then easy to place them in position on the glass for development. But, as we have just said, the simplest way, and perhaps the most satisfactory, is to cut the negatives.

F. MACCABE.—The particulars and print you sent are insufficient to enable us to offer an opinion. An inspection of the negatives and description of camera and dark slide might make the matter clear. Are you sure there is no obstruction across the lens, either inside the camera or outside.

RETOUCHING (Reply to "Hampshire").—You retain the likeness well—a most important, and often neglected, point—but your touch is too stiff and formal. Blend more softly, and keep your eyes further away from the work in hand. Each touch appears separate in its application, and this leads to mechanical hardness, and also displays the method of working too perceptibly. In a year's time you should not recognise your present finish if you adhere to the above advice.

RETOUCHING (Reply to "E. C. P.")—We cannot detect any improvement upon your last efforts, and you should have allowed a longer interval before again sending to us. Your main fault is raggedness of texture, and you also fail to model the nose correctly. You should work the necks more than you have done on this batch. Better work should show for the time taken. One good lesson from a really skilled teacher should put you on the road to nicer finish. The cabinet of young man is far and away the best for general working, but rather too fine in the touch. Do not cultivate the excessive stippled effect so loved by some firms, for, whilst leading to a pretty effect, it is generally unnatural, hard, and not a little bit like the sitter. Did you read the paragraph headed "A Caution to Retouchers," in "Ex Cathedra" of our issue of October 27? We should think a considerable amount of the character has been taken from the bearded man's forehead.

J. E. R.—Two or three of the specimens sent are good average work, the others are not. We can form no opinion of the retouching, as prints from the unretouched negatives were not sent for comparison. As you have had no experience in professional portraiture, which is quite a different thing from working as an amateur, you must be prepared to take a small salary if you succeed in obtaining an appointment.

BUSINESS DISPUTE.—I entered into a contract with a firm to supply certain photographs of certain building specified by them, as part contra account. Their limit was to value of £20; my estimate, which was accepted, was for about £19 for that work. They now want to get out of it by denying the value of them as to quality. So at last it has been agreed upon to have an independent valuer, and I ask you if your aid may be given as to a thoroughly qualified person of sufficient standing, to insure an independent verdict. They have written to me through my solicitors, suggesting Mr. —. I do not know of him, and an ordinary portrait photographer cannot, or may not, be a good judge. Would you give me your opinion, which I know would be quite unbiassed?—S. T.

As the matter in dispute is so small it seems a pity that you cannot settle it between yourselves. In a case of arbitration it is usual for each side to appoint one, to discuss the points in dispute, and settle them. At present we know of no one who we think would act for you except for a fee that would probably be considered too high in so small a matter. You might approach the Professional Photographers' Association, 57, Baker Street, London, W.

PERPLEXED.—The direct cause is, obviously, allowing the prints to remain in a heap in a damp condition, but there must be some exciting cause, and we should be inclined to look for it in the mountant or the card, and most likely it will be in the former. You do not state what mountant you use, nor when you met with the same trouble before, whether you used the same cards, mountant, etc. We shall be pleased to hear from you on this, also as to your exact method of working, length of washing, etc.

A MOUNT QUERY.—I would be glad if you could tell me where it is possible to get mounts same as sample enclosed? I have tried several of the largest English houses, and cannot get them. I think they are only to be got abroad. You will see that it is a slip-in mount for large photographs 12 by 10 and 10 by 8 prints. There is printed on the back of mount, which comes from France, Collection Defeste Muldum (this word not distinct) Prix, and a photographer's name on the front.—BLACKDOWN.

We are unable to identify the mount as that of any manufacturer known to us. Perhaps the actual maker can give our reader the information.

T. B.—Kodak, Limited, 57-61, Farringdon Road, London, E.C.

DEVELOPER.—I would be greatly obliged if you would tell me a good developer for midget negatives taken by incandescent light, for I do not seem to get very good ones by using pyro soda; it does not bring the detail out in the blacks.

Probably the negatives are under-exposed. Try the following: Soda sulphite, 2½; water, 10 gs. Add 1 oz. to 3 oz. of water, and to each ounce of this weaker solution add two to three grains of dry amidol at time of use.

RAPID.—The glazed area would give you too little top light. You might make it do for busts, but for standing figures and groups you would find yourself at a disadvantage. The extension of sidelight sideways would not help you, but in any case 16 ft. is very short for a studio.

M. PLANTIE, Prefect of Constantine, in Algeria, has prepared for Queen Alexandra an album containing a complete collection of photographs of the most picturesque sites in the country. According to the "Daily Telegraph," her Majesty, during her visit there last spring, had, it is said, expressed the wish to possess some such memento of her sojourn in the French colony. The album has been sent by the Prefect to a lady, now at Marseilles, who will transmit the present to the Queen.

Mr. T. G. AMES, late with Messrs. B. J. Edwards and Co. notifies us that he is now representing Messrs. Elliott and Sons, Ltd. of Barnet.

* * NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the best portion of the paper.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1906.

EDITED BY GEORGE E. BROWN, F.I.C.

The whole literary and advertisement contents of the ALMANAC, it is satisfactory to state, are now passing rapidly through the printers' hands. The task of producing 25,000 copies of a volume of 1,616 pages is, however, no light one, and it will be December 1 before the printed ALMANAC can be delivered to the public. Individuals who have not yet ordered should do so at once through a dealer or bookseller, otherwise they will most probably be disappointed in obtaining a copy. The features of the ALMANAC are sufficiently well known, but attention may be specially directed to certain constituents of the forthcoming volume:—

1. A *Contents*, serving as a guide to the pages, and showing at a glance in which portion a given item of information is to be sought.
2. An *Index* of nearly every individual fact, formula, and paragraph, serving to take the consultant to his subject at once.
3. *Photographic Copyright*. A popular exposition of the subject in its present-day applications.
4. *Epitome of Progress*, classified and codified. A review of the year's work in technical and scientific photography; in which everything on a given subject is assembled at one place in the volume.
5. *Contributed Articles* by leading writers.
6. *Frontispiece*, in Barnet Platino-Matt bromide paper, of Miss Billie Burke.

The Tables, Formulæ, and other features of the volume have been revised and re-arranged, and, it is hoped, will meet with the approval of every one of the 25,000 prospective readers of the 1906 ALMANAC, which in mere size, the publishers must confess, is greater than any of its forty-four predecessors.

EX CATHEDRA.

The Wrong Man's Portrait. It is exceedingly unpleasant to have one's portrait published as being one who has committed a crime; but such a thing may happen by accident. The "People," of Sunday last, contains an apology for having published, as a portrait of a murderer, that of another person of the same name, residing in the same county. It would seem that the portrait was supplied in error. This is what the "People" says:—"We much regret the error on the part of the firm from whom we received the photograph, and apologise," etc. Such a mistake as this is very regrettable, and shows that one can never know to what use our portraits may, at times, be put. It is very doubtful if a photographer who has been paid for taking a portrait can legally sell copies of it, even if the person becomes a criminal.

* * *

Frauds on the Public. On one or two occasions during the past year we have made reference to the frauds committed on the public in connection with photography, by persons going about on the pretence that they are canvassing for orders for photographers. The system followed is usually this, and the chief victims are generally servant girls. The man, after showing some excellent specimens, represents that by paying him a small sum they can have their portraits taken at a ridiculously low price at a high-class photographer's in the neighbourhood. The money is paid, and when the sitting is asked for, the dupe learns that she has been defrauded out of her money. Sometimes the money is obtained for an enlargement, at a very much reduced price; the picture is taken away, and nothing more is seen of it or the man. A week or two back one of these gentry was brought to book, and was sentenced at the West London Police-court to nine months' imprisonment with hard labour. Another stands committed for trial at the next Essex Quarter Sessions, on an alleged similar offence. Not only are the public defrauded by these people, but they cause great annoyance to the photographers whose names they have used, for when the victims go to the studio, it is sometimes difficult to convince them that they have been duped—the photographer's word often being doubted. It is a further annoyance to good-class photographers to know that men are going about, from house to house, using their names, touting for bogus orders, when they are much above that style of business.

* * *

The History of Gelatine Emulsion. The paper by Mr. J. Burgess, read last week before the L. and P., and published in this issue will, no doubt, be read as a very *ex parte* criticism of the share taken by Dr. Maddox in the evolution of the gelatino-bromide emul-

sion. We do not question the correctness of Mr. Burgess's reminiscences, even if we are unable to repress a smile at his statement of the chief claim of Dr. Maddox's paper to recognition. And then, forsooth, he would ask us to believe that the leading members of the photographic profession and trade, in supporting the Maddox memorial, were hoodwinked into regarding the paper as of some value. Mr. Burgess appears to be angry that credit has not been done him in these pages; but the *ALMANAC* of 1880, in its editorial review of the "Rise and Progress of Gelatine Emulsion Photography" is just to Mr. Burgess in describing him as having "first showed practically that excellent results were obtainable with a dry gelatine plate."

Half-tone for Christmas Cards.

It is somewhat surprising that professionals have made so little use of half-tone printing for long runs of work when the quality of a platinotype or bromide print is not required. Almost the extent to which this method of producing prints has been carried is in postcard work, election portraits, and so on, but the big Christmas card publishers have long issued beautiful little views printed from half-tone blocks, and such are the facilities offered by the blockmaking firms, that a hundred or a gross of prints on a fine-surfaced paper can be obtained for something like half a guinea. Indeed, if a number of lots are ordered at the same time, so that the minimum rate does not come into effect, the prints may cost even less than this. When more from each block are wanted, the cost is greatly reduced, an extra hundred or two costing only a few pence more. Really good original photographs should be sent to the blockmaker, and a fine-grain screen should be employed, the resulting block being carefully printed on good paper. One application of half-tone printing which suggests itself at the present moment is for private Christmas cards. Photographs of house and grounds, a recent portrait group of children, a photograph of the first baby, and so on, would form suitable subjects, and a couple of hundred cards is not at all an unusual number for many customers to order. The picture might be printed direct on to the card, or on a folded sheet as an inset. In case mounting was necessary, the best method would be to apply mountant of a readily soluble character to the backs of all the prints, allowing them to dry and then trimming, when the card would be sponged, the print laid in position, and placed under firm pressure. Done systematically, this method would be quite as rapid as ordinary mounting methods, and the results greatly superior.

Fog in the Studio.

Not only the worker in the city studio, but many whose businesses are situated away in country towns, are dreading the autumnal fog season. Some of the most up-to-date workers have adopted the system of double doors, forming a species of fog trap, and though some of the foggy atmosphere must pass in every time there is an entrance or an exodus, the double doors prevent a current of air, carrying a great deal of fog, from passing through. Care must, of course, be taken to stop all ventilation during the prevalence of the fog, and the fitting of sashes, etc., should be seen to, or the fog will subtly penetrate. This system will scarcely be used except in the largest cities, where artificial light is available, and if this light is so arranged that the sitter is illuminated while the studio between sitter and camera is as dark as possible, any traces of fog will be very slightly illuminated, and so be unlikely to produce veil on the negatives. In smaller studios, and in places where

the fog is more in the nature of mist than the dense mixture of smoke and moisture so familiar to Londoners, a thorough warming of the entire building, and especially the studio, will be found a considerable help towards the elimination of the mist. Here, again, care must be taken to see that no weak sunlight shines in to illuminate the fog particles. In foggy weather preference should be given to lenses of as short a focal length as practicable, for the reason that the nearer the lens is to the sitter the less intervening moisture-laden atmosphere will there be to cause deterioration of the brilliancy of the image. Care must be taken to avoid over-exposure, too, and it may often improve negatives taken under foggy conditions to stop development before any veiling of the shadows occurs, and then intensify afterwards to obtain sufficient printing strength.

The Kokka.

In a recent issue we drew attention to "The Kokka," a high-class illustrated monthly dealing with the fine and applied arts of the Far East. It is published in Tokyo, at two yen a copy, or about 4s. in our money, and even at this price compares very favourably with any English production on the same lines. Its value must be considerable to the student and collectors, since it illustrates by means of wood engravings in colours and collotype, works of Japanese art, in private hands, or in temples, which the traveller is never likely to see. The title indicates this to a certain extent, as we understand that "Kokka" means "flowers of the nation." A perusal of the latest number sent for our inspection reveals a wealth of beautiful designs and reproductions, characteristic of oriental subtlety and mystery, but it is interesting to note that the whole literary contents—from the pens of eminent Japanese art critics—is in excellent and erudite English. At a time when all things Japanese are being studied in this country with increased interest and respect, the pronouncement of one of the writers in the present number on the "characteristics of Japanese art" should throw an interesting side-light on the art-motive as it presents itself to a people who are universally acknowledged to be a race of artists. He says:—"Our art is generally inclined to present a broad, bird's-eye view of a scene. Consequently in one and the same painting there are represented scenes of all sorts, distant mountains, a flowing stream, a tortuous path, a towering edifice, a half-way village, etc., a peculiarity which must strike the western eye as something fantastic and incongruous. Just here, however, lies the peculiar advantage of the Japanese theory of landscape painting, for a scene of the most complicated nature can be treated with remarkable ease and freedom when the chief sentiment of the picture is not concentrated on any one particular object, but finds expression of the organic relation of the whole." We gather therefore from this that the Japanese idea of pictorial art is primarily decorative. Subject and motive, unlike the ideals of the Occidental, being relegated to a position subordinate to the scheme of line and form.

Storing Apparatus.

With November comes the end of the photographic season, so far as outdoor work occupies the majority of workers. Seeing that valuable apparatus will lie idle for some months, it is worth while to consider how, and where, it should be stored. Too often the owner finds when it is unearthed for use in the spring that it is not in the same condition that it was expected to be. Then it is recognised that had a few simple precautions been taken at the time it was put away, and had it been differently kept, things would have been quite different, and, some

times, much inconvenience and some expense avoided. Very frequently the apparatus is put away in just the same state as it was when last used, perhaps damp, with the result that the wood-work of the camera, and of the slides more particularly, has become swollen, and the glue joints loosened. Even with the best seasoned wood, which is always used in the more costly apparatus, it will not stand several months continual exposure to damp without suffering to some extent. Damp, again, will seriously injure the bellows. The glue securing the leather to the canvas foundation will become softened, and, as most are aware, leather, if kept long in a damp place, is liable to become mouldy, and the mildew spots, when cleaned off, if they are deeply rooted, leave unsightly marks, even if they do no further harm. Metal parts are also liable to suffer from oxidation. Although the hinges are of brass, the iron pins of them get rusty, and then the hinges work stiffly, and often, after a little while, the wire breaks.

* * *

Seasonable Precautions. All the troubles enumerated above may be avoided with little or no labour to the owners of the apparatus, and here are a few hints that may be useful to some:—In the first place the camera, with the bellows fully extended, should be allowed to stand a day or so in a dry room, say an ordinary living room, so that any undue moisture can escape. The dark slides, with the shutter drawn, should be similarly treated. After resting for a few hours, or a day, all the parts should be carefully dusted, the pins of the hinges receive a drop of olive oil, and the apparatus packed up. It is a good plan to dust the bellows, in the folds, with a little French chalk, to prevent sticking, to which the varnish is sometimes liable when two surfaces are kept for a long time pressed in contact. If the apparatus is contained in a leather case it is a good plan to see that this is thoroughly dry also. When all this is done, it is well to tie the whole up in brown paper, as that will protect the case from dust and dirt. A word will not be out of place with regard to storage. It goes without saying that the place should not be a damp one; neither should it be abnormally dry, as under these conditions ill-seasoned wood may suffer by shrinkage. The best place to keep the apparatus during the months of storage is that where the conditions of an ordinary living or bedroom prevail. If the precautions we have enumerated are taken, the apparatus may be put away with the assurance that it will be found, when next required for use, as fit for work as when put away.

PRINTING PROCESSES.

XV.—TONING BROMIDE PRINTS.

The desire for warm tones on bromide prints was probably, in the first place, induced by the feeling that, whilst the surface was extremely satisfactory, the cold black or grey tones were not always suitable for every subject. There may have been also a desire to emulate the rich warm tones of carbon without having the necessity to resort to the transfer process. But we are not so much concerned with the origin and history of the various toning processes now in vogue as in their practical application. The methods for obtaining warm tones are very numerous, but the subject can be much simplified if we omit from serious consideration those processes which do not yield permanent prints. Foremost among these is uranium toning, one of the earliest, one also giving a convenient range of tones. But whilst in some cases prints treated by this method have stood the test of

years, others have been known to fade within a few weeks, and there seems to be no reliance to be placed on any given method of working.

Another process, which must be viewed with suspicion, is the so-called platinum substitution process suggested by Mr. C. W. Somerville. We have before us as we write some prints treated by this process, which, although not six months old, are now of a pale lemon colour in parts, and still fading. The vanadium process for obtaining green tones, suggested by the same experimentalist, is also open to very grave doubts, as some of our trial prints have undoubtedly faded. Further than that, the final tone of the print is dependent on the amount of washing that it receives. After toning it is distinctly blue, by washing it becomes green, by still further washing an olive green, and finally the green tone disappears altogether. It would seem reasonable to lay down the axiom that any processes of toning bromide prints which leaves as a constituent of the image a substance which is readily soluble in water cannot be permanent.

MM. Lumière and Seyewetz have proved that the lead and cobalt methods of toning bromides give an image of which a large portion consists of silver chloride. These therefore cannot be considered permanent.

The copper toning process certainly gives more permanent prints than the uranium, but is open also to the objection that the final tone is dependent on two salts, which can be readily dissolved by weak alkalies, even such as hard tap-water. It is but fair to surmise that, as it is impossible to preserve a bromide in an absolutely anhydrous condition, and the air may contain traces of ammonia, there is a loophole for change of colour.

Practically the only processes for obtaining warm tones which can be relied on are those in which the final image consists of sulphide of silver. Before entering upon these processes there are one or two points which must be considered. The first question is the effect of the original developer upon the final tone. That this has some influence cannot be gainsaid, and, assuming that one of the sulphide toning methods be adopted, the following developers give a range of tones progressing from cold to warm—amidol, metol-hydroquinone, rodinal, metol, ortol, ferrous oxalate, and hydroquinone.

There are two principal methods of sulphiding the image, the one in which the original image, consisting of metallic silver, is treated, and the other in which the image is converted into a silver salt and then converted into sulphide.

The former process is usually effected with a mixture of hypo and alum, either cold or warm, and of the two the latter is much to be preferred, mainly on account of the saving in time. For this process undoubtedly the best results are obtainable when the print is developed with ferrous oxalate. This gives warmer tones than any other developer, and if the hypo-alum bath is prepared as suggested below, sepia and purple-brown tones are readily obtained:—

Hypo	3½ ounces.
Powdered alum	½ ounce.
Boiling water	20 ounces.

Dissolve the hypo in 15 oz. of water, the alum in the remainder, mix the two solutions, and then add

Silver nitrate 10 per cent. sol. 60 minims.

Stir the mixture well, and allow to get quite cold. Then heat the solution to 120-140 deg. Fahr., and allow to cool. Repeat the heating and cooling three times. When required for use, the bath must be heated to 100-120 deg. Fahr. The print, which should be alumed, washed, and dried after fixing, is bodily immersed, and left for from fifteen to twenty minutes.

Some workers prefer to use the plain alum-hypo bath alone, either heated or cold. In the latter case the operation of toning takes a very long time—it may even run into days—and without the addition of the silver the tones obtained are not quite so rich.

There is no fear that the print may suffer from the raised temperature, though it is frequently advised that the print should be immersed in the cool solution, and then the temperature gradually raised. There is, however, no practical difference in the results.

The other process of sulphiding is, as already stated, the conversion of the image into a salt of silver, such as the ferrocyanide, the chloride, bromide, or iodide, and then converting this into sulphide by the aid of a solution of sodium sulphide. It is obvious that a solution of sulphuretted hydrogen might be used, but the stench of H_2S is far more unpleasant than in the case of the sulphide, and but little difference is seen in the final result; possibly the tones with sulphuretted hydrogen are slightly warmer.

It is as well to recall here the warning given by Mr. J. B. B. Wellington as to the effect of the sulphurous fumes on sensitive materials, particularly printing-out paper; therefore these toning methods should not be carried out where such materials are stored.

The first step in these processes is the bleaching of the image, which may be effected by using chlorine, bromine, or iodine solution, but to many the smell of these is extremely irritating and unpleasant, and equally good results may be obtained by using other oxidising solutions. We may convert the silver image into the haloid, either by using an acidified mixture of bichromate and an alkaline haloid, or with a mixture of potassium ferricyanide and haloid. The advantage of the former is that it at once destroys all traces of hypo, so that the print need not be so thoroughly washed: that of the latter is that the bleaching is more rapid. There is not much choice between the two.

As a typical formula for the bichromate bleacher we may use

Potassium bichromate	25 grains.
Alkaline haloid	50 grains.
Sulphuric acid	50 minims.
Water to	10 ounces.

The alkaline haloid may be either salt, potassium, or ammonium bromide or potassium iodide.

For the ferricyanide bleacher we may use

Potassium ferricyanide	$\frac{1}{4}$ ounce.
Alkaline haloid	180 grains.
Water to	10 ounces.

The question as to which is the best haloid to use must be decided by the operator himself. The coldest tones are obtained by the use of a chloride, the warmest by a bromide.

Instead of using a haloid the image may be converted into ferrocyanide of silver by using the above quantity of ferricyanide and rendering distinctly alkaline with ammonia; and this gives somewhat cold tones.

The sulphide solution may be kept as a stock solution, but there is sometimes a variation in the results obtained, so that it is better to make a fresh solution as wanted:—

Pure sodium sulphide	1 ounce.
Water to	20 ounces.

As soon as the print is immersed in this solution the change of colour will begin and be completed in a very short time, but it is as well to leave the print for a minute or two and then wash thoroughly.

Before leaving the sulphide process, it may be as well

to point out that warmer tones are obtained by bleaching the print in copper bromide or chloride, the formula being

1. Copper sulphate	200 grains.
Potassium bromide	200 grains.
Or salt	200 grains.
Water to	10 ounces.

The print must be thoroughly free from hypo, immersed in the above bath till thoroughly bleached, and then rinsed two or three times, immersed in a 1 per cent. solution of nitric acid, and washed, and then treated to the sulphide bath.

Another process, in which the final image consists, wholly or in part, is that in which the bleached print is treated with a 1 per cent. solution of Schlippe's salt (sulphantimoniate of soda), rendered alkaline by caustic potash or soda. Somewhat yellower tones are obtained by this process, but it is an open question as to whether the results are permanent. Some prints treated by this process over ten years ago seem to be now in their original condition, whilst others have markedly changed in colour; this being doubtless due to the complete or incomplete conversion of the silver salt.

An important point to be considered when choosing one of these toning methods, is the effect on the gradation and depth or intensity of the image—that is to say, whether the print is reduced or intensified.

The hypo-alum method certainly reduces the print considerably, therefore prints must be over-developed. The sulphide method does not reduce nor intensify, but as the colour of the image is not so intense as when black, a rich print must be obtained, otherwise the shadows will be flat and poor. The copper and Schlippe's salt methods intensify the print, the former, however, not very appreciably.

As regards the colours obtained, opinions on this point differ, and some will prefer the sepia of the sulphide, whilst others the more purple tone given by the hypo-alum with silver bath. This, used after ferrous oxalate, gives the nearest approach to the purple brown of a P.O.P. print that we have yet obtained.

So far as we are aware, there is no satisfactory method of imparting a permanent green tone to bromide prints, and certainly such a tone is rarely required. The same might also be said of blue tones, but these can be obtained by immersing the print in

Potassium ferricyanide	90 grains.
Strong nitric acid	48 minims.
Ferric ammonium citrate	44 grains.
Water to	20 ounces.

When the desired tone is reached the prints must be well washed until the whites are clear. There is some danger of the whites being stained, as it is difficult to prevent the formation of basic iron salts in the pores of the paper.

Rich brown and purple tones can be obtained by bleaching the print in the ordinary mercuric chloride solution, as used for intensification, well washing and then toning in an ordinary sulphocyanide of gold bath. In the case of rusty bromide prints, such as are often obtained by the use of too much bromide in the developer, or over-exposure, a strong sulphocyanide of gold bath will considerably improve the colour, and it is quite possible to save many a print by this method.

The above may really be said to be the practical processes of bromide toning. Changes may be made in the bleaching solutions, or in the strengths of the sulphide solution, or in using other sulphides than the sodium; but in practice they offer but few, if any, advantages.

COLLODIO-CHLORIDE PAPER.

[In reference to the recent letters in our correspondence columns on the stability of prints made on collodio-chloride papers, the following notes, by one who can claim some eight years' continuous practice in working the process, may be offered as opportune. The fact that the stated experience of those printing in collodio-chloride is contradictory is sufficient ground for the view that the technique of the process only requires to be mastered to remove the slur of impermanency which some workers have felt compelled to cast upon it.—EDS. B.J.P.]

The paper can be had matte or glossy, and various colours are easily obtained—from red to grey with the cold bath only, and with platinum and gold, the most beautiful black (carbon black in expert hands) that is more soft and delicate and has finer details and depth in the shadows than the platinotype process itself. Yet, with all these advantages, there are drawbacks that make professionals chary of working the process.

The Question of Permanency.

The chief drawback is problematical permanency. Problematical is the correct qualifying word, for whereas some C.C. prints appear to be absolutely permanent under severe tests, others fade, go blotchy, or are covered with spots that sometimes appear a few days after toning, though the prints have been apparently treated in all respects in a fashion similar to that of others of proved permanency. That the question of permanency is of the utmost importance to the professional there can be no gainsaying. A good print is an advertisement of value for all time, but a faded, or, in any way deteriorated, print will do more harm than twenty excellent photographs will do good.

Single Versus Double Bath.

From comparative tests made in a practical and not a theoretical way, I found that the paper toned in a single gold bath was less permanent than that toned in the gold bath, followed, after washing, by the chloroplatinite of potassium bath, though the former was not susceptible to spots, partial fading, and sudden deterioration, as is the latter.

The single-bath prints are, in fact, to be depended upon, since, when made with any degree of care, the fading is not apparent for twelve months; and, if then, takes the form of a slight change of tone which gradually gets worse. On the other hand, prints toned in two baths, when made properly, are to all intents and purposes permanent, showing no change after two years' exposure to sun, damp, and sea air, though other prints from apparently no explicable cause will be covered with yellow spots within twenty-four hours, or, maybe, the black tone will turn brown in places after a few weeks.

Defects and Remedies.

A few of the faults common to the process may be detailed as follows:—

Red patches, often taking the form of a finger or thumb mark. They are due to grease on the surface of the print which prevents the solutions acting. They occur through careless handling, or handling with hot or dirty hands. Only a knack of handling the paper is required for their thorough prevention. An old printer will probably not have more than one print in ten thousand spoilt in this way. To minimise the likelihood of these marks appearing, after about ten minutes' washing, the prints may be passed through a bath of $\frac{1}{4}$ oz. bicarbonate of soda to 80 oz. of water. A further washing for five minutes in clean water must follow.

Red spots, other than those caused by grease seldom occur. If they appear it may be due to iron rust in water, or too little washing before gold, or too strong gold bath.

Bronzing is due to too hard negatives, or to too short immersion in the platinum bath. The single gold toner requires a much less contrasty negative than the double bath.

Blisters appear when the baths are of varying temperatures. In winter the prints are sometimes one mass of tiny blisters. They usually dry down, however, and seldom give further trouble.

White spots appear only on the prints toned in gold only, and may be due to too strong hypo, or the prints have been allowed to lie still in the fixing bath. The prints must be continuously moved.

Cracking is at times a serious source of trouble. It occurs chiefly in cold weather and with fresh batches of paper. Fresh tubes should be opened and allowed to ripen for a few days before use. There is no actual remedy.

Black spots can usually be traced to the use of zinc shapes for cutting oval and circular prints, and are formed by the minute particles of zinc falling on paper before toning. All C.C. prints should be toned before cutting out, not only because of black spots, but because the edges of other prints chip and break off. Be sure that when drying off only the best pure blotting paper is used. I have had a print returned to me with most distinct signs of reversed printing on the film side, due probably to momentarily laying a printed page on the pictures before they were thoroughly dry.

Yellow Spots.

All the above faults, however, are of little consequence, easily averted, or of infrequent occurrence. The *bête noir* of the collodion printer is the yellow spot, whose appearance is shrouded in mystery. The known causes are many, but, unfortunately, unknown causes appear to step in when the former are eliminated. Yet, I will endeavour to detail the avoidable risks which are mostly peculiar to the double bath process. The single gold bath seldom produces these spots, and, therefore, as already explained, is more reliable, though, not in a way, so permanent, and certainly not capable of producing the black tones that are the chief attraction of the C.C. paper.

The first washing should be thorough. The first toning—preferably in the borax bath—does not have much influence on the production of spots, but the bath should be slightly alkaline. Washing after toning must be thorough, if the spots are to be avoided. Toning in the platinum bath is not to be feared if the previous washing has been well done, but washing after the platinum is absolutely the most important part of the process. Slackness in carrying out this washing is the great cause of spots and fading; the acid from the platinum bath must be eliminated before fixing if permanence is of the slightest importance. To make assurance sure add some borax solution, or carbonate of soda to the last washing water but three.

Fixing and After.

The fixing bath, as has been pointed out by a correspondent, is seldom advised strong enough by the makers. They recommend 1 oz. to 20 oz. of water, and five minutes' washing, whereas for nearly ten years I have used 4 oz. of h-no to 20 oz. of water, and fixed for a quarter of an hour without the least deterioration.

Be sure that the hypo is alkaline, and, to ensure this, add a few ounces of borax or carbonate of soda solution to it. Also be sure that your hypo is perfectly pure and free from foreign matter. To keep it so, store it so that no impure air can reach it.

Washing after fixing must be of the most ample description. Certainly give ten minutes' hard washing to get rid of the surcharge of hypo immediately after fixing, and wash for at least two hours' in running water, or, preferably, give a further half an hour's hard washing. Now dry off on blotting, or on clean sheet for cutting out. It is better to cut out before the prints are bone dry, and to place the cut out prints in water,

as the paper when once it has become thoroughly dry is liable to crack and to prove refractory, where sticking flat to mount is concerned. Mount with clear, pure starch, made same day, and lay to dry.

Having arrived so far, and judging from other processes, one might reasonably expect that there would be no further cause for fear; but, unfortunately, the supposition is wrong, for at this advanced stage the chance of yellow spots is very great, more especially if the weather be at all damp, or if the season be winter.

The Importance of Quick Drying.

As was pointed out in the JOURNAL about two years ago, and as a recent correspondent has surmised, one of the most frequent causes of yellow spots and cases of fading is the too slow drying of prints. After mounting, the prints must be made bone dry as quickly as possible—if the weather be at all damp the prints *must* be dried in a heated room. The only satisfactory thing about yellow spots produced by slow drying is that they usually show in the course of twenty-four hours. If, unfortunately, you get these prints delivered, the result is disastrous, for the appearance of a print suffering from "the yellow peril" is indeed appalling.

The curious part of this cause of failure is that though slow drying has been recognised in America as a frequent cause of these spots, and hot rolling with a card over the face of the

prints advised as a further preventive, yet the German and English manufacturers say nothing about it in their somewhat meagre directions.

The Non-effect of After-damp.

Another peculiar feature is that though dampness, if prolonged, has an extraordinary effect on the freshly-mounted print, yet when once dry, damp, or even actual wetting, has no effect. I have specimens, first made six or seven years ago, and then exposed in showcases not remarkable for their weather-tightness—in fact, dew frequently soaks the mounts through and through, and this is alternated by strong sunlight—yet, after two years of this, and the remainder of the time on a wall, the prints are as good as the day they were made. In fact, never have I had the slightest trace of fading in showcases, yet prints which may have been left lying about in wrappers are occasionally returned in a heartbreaking condition.

The general conclusion is that collodio paper must be treated with the care due to its special and peculiar susceptibilities. Of course, it is the height of folly to take it up as "just another sort of P.O.P." Considering its comparative newness in this country alongside P.O.P., there is reason to suppose that expert printers have yet to discover one or two things about it, and many workers of it probably blame it for faults which they would never discover if they would recognise a few fundamental facts in regard to the paper. W. FOSTER BRIGHAM.

THE HISTORY OF GELATINE EMULSION PLATES.

[A paper read before the London and Provincial Photographic Association on Thursday, November 2.]

It is with genuine pleasure that I respond to the invitation you have given me to relate the history of gelatine dry plates. The story I have to tell you is the correct version of a tale which has been very much garbled and distorted, not intentionally, I am quite sure, but through carelessness.

Dr. Maddox's "Discovery."

As you all know, Dr. Maddox was awarded the honours of the invention by the Scribes and Pharisees of the profession. They presented him with a gold medal and £400 as a token of their gratitude for the immense benefits he was supposed to have conferred upon the lovers of the gentle art of photography. Every man who contributed to that testimonial did himself credit. He believed what he was told, and demonstrated practically that he had some sense of benefits received. The present generation can hardly imagine how great those benefits are. Those only have a lively sense of the boon they enjoy in using the gelatine plate who can remember the difficulties and vexations of the old wet-plate method, or the primitive dry plate, which was so slow that a man could sit down and smoke his pipe while the landscape was impressing itself on the fettered silver bromide.

But I wonder how many of the contributors to the Maddox testimonial took the trouble to inquire just what the doctor had done. The general idea seems to be that he made a plate similar to those used now, but not quite so good. This is an entire mistake, but Dr. Maddox is not to blame for this. He was perfectly honest in his account of what he did. He laid no claim to having made a great discovery; he simply recorded an abortive experiment which taught one thing excellently well, and that was how not to do it. I could make the world a present of hundreds quite as good if they were worth printing. But see how gullible men are. In Jerome Harrison's "History of Photography," page 63, he says: "Three men, Harrison, Sutton, and Maddox, had clearly recognised the pos-

sibilities of gelatino-bromide emulsion." They had done nothing of the kind, or they would never have dropped it. They met with difficulties, and ran away. Victors do not funk at the first obstacle they meet, and men who clearly recognise great possibilities persevere. The historian goes on to say: "Two of them, Harrison and Maddox, actually prepared such an emulsion with a marked degree of success." Yes; the success was so great that neither of them ever touched it again, and by recording their failure, warned future comers off the road. Harrison, writing in THE BRITISH JOURNAL OF PHOTOGRAPHY in January, 1868, after describing how he made his emulsion, says: "The picture came out very rapidly, and was of great intensity, but the rough and uneven surface of the film 'made it worthless, and there was an end of it.'"

Does this sort of thing advance our arts? It was a decided discouragement, and yet the history proceeds: "At least one worker took the hint," and in the pages of the English trade journals for July, 1873, the following advertisement appears, which was the one reproduced a few weeks back: "One worker took the hint!" Which hint? That it was worthless? The man who said, "It was worthless," came much nearer to success than Dr. Maddox did, though he is set on a monument as the originator of gelatine dry plates. I am very glad to say that I was fortunate enough to miss those precious hints, and never heard of either of them till my own emulsion was beginning to make a stir. And I was accused of meanly trying to sell what the other generously gave away.

Dr. Maddox's Formula.

Let us be perfectly fair! We will have a look at the wonderful experiment which is supposed to have put me on the road to success. On page 61 we have it: "Thirty grains of gelatine were swelled in cold water." Was that the hint? Why, gentlemen, gelatine was used in photography before collodion. "Then it was dissolved by heat, four drachms of pure water

and two drops of aqua regia being added. To this solution eight grains of cadmium bromide and fifteen grains of silver nitrate were added, forming a fine milky emulsion of silver bromide. Without further treatment this was spread upon glass plates and dried."

Now mark what the doctor says: "The plates were tested by exposing them beneath negatives, and gave a faint but clear image when developed with a plain solution of pyrogallie acid; intensification with pyro and silver followed."

There is no suggestion here or hint of any kind that negatives could be made from such plates at all. And the fact is, they cannot be. I defy any man to make a negative by that formula, and, so far as I know, that is the only scrap of information Dr. Maddox ever imparted, and by the faithful it is supposed to be the fountain from which the marvellous expansion of photographic business we are familiar with to-day has flowed. Gentlemen, I will tell you a secret. The great virtue of that article was that it filled a page in that really excellent paper, *THE BRITISH JOURNAL OF PHOTOGRAPHY* when the Editor was in distress. He, good man, was so grateful to his friend for coming to the rescue when he was hard up for copy that he pushed forward this claim when the opportunity came, and though Dr. Maddox never achieved greatness, it was thrust upon him by his admirers. Surely no man on this planet was ever so munificently rewarded for so slight a service. But photographers are pre-eminently a generous lot; it is a joy to be one of them.

Now, if Mr. Traill Taylor could have destroyed all the back numbers of his own journal this action of his might have passed unchallenged. He forgot Harrison and Sutton and Gaudin, who did much more in the way of suggestion than the editor's pet ever dreamt of.

The Obstacle to Emulsion Making.

It is a very extraordinary thing that in this world cleverness is much more common than perseverance. Many men got as far as Maddox and foundered just as he did. I met in my experiments the bogey that scared poor Harrison, but I happened to know the cause and was not frightened. It was the crystallisation of the salts formed by the decomposition of the silver nitrate, which was easily removed by washing the plates in water after the emulsion had set firmly; but this was a troublesome business, though it made good plates. One evening, after I had washed and put about two dozen of plates in the drying cupboard, each standing on a piece of blotting paper to absorb the drainings, I went out for a walk, with dry-plate making on the brain, feeling very weary and wishing that art was easier. I was too tired to enjoy my walk, and sauntered along, hardly knowing what I was doing, when a thought electrified me—a thought which was worth a million of money. It was simply this:—Why not wash the emulsion before putting it on the plates? When set, gelatine is insoluble in cold water. I shouted "Eureka!" and rushed home to try it. But there was still a ticklish problem to solve. When my emulsion was made and had set firmly in a gallipot, it looked like a nice blanc-mange. How was that stiff mass to be broken up so finely that the water could dissolve the salt out of it as easily as from the surface of a coated plate? This problem, which has been a difficulty with many workers, was solved for me as if Providence had arranged it all beforehand. While I was discussing this question with myself, my eye caught sight of some canvas my wife was working on for a pair of slippers. The meshes would allow only a thin thread to pass. The very thing for my purpose! The sensitised jelly was coarsely broken up, put into a canvas bag, and squeezed under water. It went through and sank to the bottom of the pan in very fine threads. One hour in this water removed every trace of salt. The water was filtered away as completely as possible, and then followed the usual coating and drying. The result was a perfect gelatine dry plate much quicker than anything which had been done at

that time, and, to this day, nothing better. Quicker, certainly, but not better.

I very much under-estimated the speed of my first plates. Indeed, this was the general stumbling block in the early days. It was hard to believe that light could work its wonders so rapidly. Therefore, over-exposure was the rule, and flat negatives the result. The plates were as good then as they are now, but how to use them had to be learned, and it took seven years to teach the public the value of dry plates. But from the day that first advertisement of mine appeared, hundreds of eager experimentalists went to work with new ideas of the possibilities, and triumphed.

The Invention of Bromide Paper.

Everybody believes in gelatino-bromide plates now. What do you say to bromide paper? I see in yesterday's "Daily News" that the veteran inventor, Sir J. W. Swan, is credited with the honour of giving our snapshotters their quick plates and their quick-printing bromide paper. We are all greatly indebted to Sir J. W. Swan for many good things; but, if you please, your humble servant was the inventor of bromide paper, and was superintendent of Morgan and Kidd's factory, at Greenwich, for the first year of its existence, and I wrote the first book on the treatment of bromide paper for that firm. It was entitled, "The Gelatino-bromide Worker's Guide."

I am aware that Sir J. W. Swan claims to be the originator of the present method of conferring speed upon emulsions by means of heat. I had an interview with him once, when we talked the matter over, and he described a series of experiments which led him to the conclusion that the only limit to the speed obtainable was the comparative slowness of our shutters. But, I think, that was after Mr. Bennett had produced his sensational pictures. It is difficult to say how much we owe to-day to the vast improvement in developers. But it must not be forgotten in judging these matters that the mechanical law which states that what is gained in power is lost in time holds good in photographic chemistry. What is gained in speed is somehow lost in quality. Gentlemen, that is all I will say at present on gelatino-bromide emulsion plates. But let me have a few words on colour photography.

A Process of Colour Photography.

For many years past the dream of our craft has been the production of pictures in all the glories of Nature's tints. By the primitive colour combinations some wonderful things have been done, but there is no such thing as colour-photography yet. All the single prints are monochromes. I have carefully studied the three-colour process, but the difficulties have seemed to me so formidable that I have never attempted anything in that line, because my aim has been to devise a process which can be worked in the studio without the operator having to learn a new trade, or provide himself with unfamiliar apparatus. I think I have, at last, after many heartbreaking failures and disappointments, succeeded fairly well in working out a new process for producing all the colours of Nature, in proper gradation, by mechanical means.

I have two experimental specimens with me, which I submit to you, still imperfect, but full of promise. Much better things will soon be done when practice has given me more confidence. I believe that when younger and more skilful hands than mine deal with this new process, pictures will be produced that the Royal Academy will not despise. J. BURGESS.

WE have been informed that Mr. F. E. Jones, who was for five years with Messrs. T. Illingworth and Co. and four years with Messrs. L. Trapp and Co., has joined partnership with Mr. E. von Aix, also late of Messrs. Trapp and Co. They have opened a business as photographic materials dealers at 22, Gray's Inn Road, London, W.C., under the style of F. E. Jones and Co.

THE WEEK IN HISTORY.

The Classic of Orthochromatism.

PRECISELY thirty-two years ago to-day was published a paper to which reference has been made by photographic writers more frequently than to any other, viz., that of Vogel on the sensitiveness of plates to the rays usually thought to be chemically inactive. This classical paper was translated in full in "The Photographic News" of December 12, 1873, when it was seen that Vogel's discovery was prompted, or, perhaps, I should say, predicated by English activities in plate-making. The facts as stated by Vogel are as follows:—He received from England some Wortley dry collodio-bromide plates, and found to his astonishment that they were more sensitive at the line E in the green of the spectrum than at F in the blue. He proceeded to experiment further on silver bromide exposed to the solar spectrum, and employed his silver bromide in two ways: (1) Wet, and with solution of silver nitrate adhering to it, and (2) dry, prepared by washing off the silver nitrate and drying the bromide. It was found that the dry bromide had a much greater sensitiveness for colours. With the wet bromide of silver a strong action was observed between G and F (in indigo and blue), but at F it vanished completely. The diminution of sensitiveness from blue to green, observed by Vogel on German plates, being absent from the Wortley plates, it occurred to him that the difference was due to the uranium nitrate and yellow colouring matter contained in the latter, and he found that a Wortley plate, after washing, did not exhibit this increased sensitiveness to green. Impregnating silver bromide with a red dye, Coralline, it was found that the plates were almost as sensitive in the yellow as in the blue. I think I may quote the remainder of Vogel's paper *verbatim*. He writes:—"I had, therefore, discovered a method of producing bromide of silver plates which could be acted upon quite as vigorously by a colour held to be bereft of chemical action—as, for instance, yellow—as by a colour such as indigo, which hitherto has been considered to exert the greatest chemical action. After these experiments I was led to hope that any other dye-body capable of combining with bromine, and which would absorb red vigorously, would also heighten the sensitiveness of bromide of silver for the red rays. Such a substance I found among green aniline colours. These absorbed vigorously the red rays midway between D and C. The absorption stretched with greater concentration further towards D, yellow, green, and blue passing through almost intact. A collodion tinted with this aniline green was found indeed to be sensitive into the red. The sensitiveness diminished from indigo to yellow, and then increased, and on that spot where the absorption band had been remarked there the film was most sensitive to red."

"From these experiments we may conclude, I think, with tolerable accuracy, that it is possible to render bromide of silver sensitive to any desired colour, improving its sensitiveness for certain colours. It is only necessary to add to the bromide of silver a suitable dye which absorbs one chosen colour, but not the others. Perhaps we shall get so far as to photograph the ultra-red spectrum just as we have depicted in the camera the ultra-violet. The photographic inactivity of certain colours, hitherto assumed, which is so often a stumbling-block, would then be obviated. In how far the results are of practical importance the following experiment will show:—A blue band upon a yellow ground was photographed. With an ordinary

iodide of silver collodion plate I obtained a white band upon a black ground. With a bromide of silver Coralline plate upon which blue and yellow acted with equal power nothing could be obtained. I foresaw, and for this reason, I put in front of the lens a yellow glass plate which absorbed the blue light, and allowed the yellow rays to pass through unimpeded, and then I was enabled to obtain, after a sufficiently long exposure, a dark band upon a light ground."

Mirror and Prism.

If anybody is interested in the first use made of the prism for the re-reversal of the image of the lens, one must turn back almost to the beginning of photography. And, of course, it was only natural that the single reversed Daguerreotype should at once suggest the need of such a device to the opticians. Hence we find it the subject of a brief note by M. Cauche on November 11, 1879, before the Paris Academy of Sciences. M. Cauche stated his preference for the prism over the mirror on account of freedom from distortion.

Washing Emulsions.

On Tuesday next another step forward celebrates its thirty-second anniversary, for it was on November 14, 1873, in THE BRITISH JOURNAL OF PHOTOGRAPHY, that the necessity of removing the products of interaction of the silver nitrate and the haloid salt from an emulsion was pointed out. Silver nitrate and potassium bromide, as every schoolboy knows now, give potassium nitrate as well as silver bromide; but this fact did obtain notice in the journals until first remarked by Mr. J. King, of the Bombay Civil Service. Having described the preparation of an emulsion, Mr. King writes:—"The result is a beautiful emulsion containing bromide of silver, a trace of nitrate of silver, and nitrate of potash, which if spread upon a glass plate will give a film fine enough when wet, but which on drying is covered with a wonderful web of crystals, through which nothing but a scarred and seamed negative can struggle into light." Mr. King proposed to remove the crystalline nitrates from the emulsion by the tedious process of dialysis.

The First Pyro-Ammonia Developer.

You have to go back a long way to the genesis of the pyro-ammonia developer, the most lasting of developer varieties, and still the one to which many of us can see no reason for giving the go-by. It was Major Russell, in THE BRITISH JOURNAL OF PHOTOGRAPHY for November 15, 1862, who first suggested it as an improvement for the dry or "preserved" collodion plate. His developer, of course, was a sort of acid silver intensifier, and his use of ammonia was suggested by its employment for fuming dry plates. "Having read," he writes, "the accounts from America of fuming dry plates with ammonia, I set about examining the capabilities of this agent with very promising results. . . . Thinking that the developing action of the fumes of ammonia must be due to their action on the tannin, the first thing I did was to try the effect of mixing a small quantity with a solution of pyrogallol, which is much more unstable. On mixing the pyrogallol and ammonia, and immediately pouring it on an exposed plate, its developing action is very energetic, not only in bringing out the image after very short exposure, but even in some cases producing a considerable though insufficient amount of intensity. HISTORICUS."

WARWICK Competitions.—The result of the October competition is as follows:—First prize, £10: James Moore, Esq., 57, Ellesmere Road, Stockton Heath, Warrington, "Organ Screen, Chester Cathedral." Donation, £5: To the Warrington Photographic Society. Second prize, £5: T. W. Sharpe, Esq., 85, Primrose Terrace, Glossop,

"Font, Glossop Parish Church." Donation, £2 10s.: To the Glossop Y.M.C.A. Photographic Society. This being the last of the series of monthly competitions for the season, a further donation of £10 has been handed to the Belfast Y.M.C.A. Camera Club, who have supplied the largest number of competitors.

THE USE OF PERMANGANATES IN INTENSIFICATION.

[A Communication to the Royal Photographic Society.]

PERMANGANATE has changed its position nowadays, as far as intensification is concerned, and has evolved from auxiliary to principal. Thus we find that many years ago it was used in connection with an iodine method of intensifying; the negative was "bleached" in a solution containing .2 per cent. of iodine and .4 per cent. of potassium iodide, i.e., left until it had assumed a bluish-green tint; it was next immersed in a 3 per cent. solution of potassium permanganate, when the silver iodide produced in the first process caused the precipitation upon the image of manganic oxide. The treatment with permanganate was, however, only of secondary importance, the chief intensification being caused by the increased opacity of the partly rehalogenised image.

Some time ago the use of potassium permanganate was suggested with subsequent development with ferrous oxalate, the red deposit at first formed being decomposed by the oxalate, and manganic oxide or low manganese compounds being formed which gave the required intensification.

By combining partial rehalogenisation, however, with the action of permanganate, a better effect is produced, and the result is an intensification which is of especial advantage in the case of under-exposed negatives, as the details in the shadows are brought up in a most satisfactory way.

The permanganate solution is prepared with hydrochloric acid, and

therefore contains a small percentage of chlorine, as can be at once detected by its smell. The proportion of permanganate to acid may vary from 2: 2 to 2: 1, the latter being most satisfactory.

PERMANGANATE BATH.

Potassium permanganate	2 grammes.
Hydrochloric acid (conc.)	1 cc.
Water	100 cc.s.

The negative, after having been thoroughly washed, is placed in this bath for a period between one and three minutes, during which time the image is transformed into a reddish-pink, and apparently loses very much in density. The clear portions become chiefly discoloured, but no chemical effect seems to take place in them, as on subsequent development they again become clear and white.

A short rinse only, in water, is advisable between the use of the above bath and redevelopment; too long washing appears to lessen the intensification.

Any organic alkaline developer may be used, but hydroquinone with caustic soda is recommended. The red plate, when immersed in the developer, quickly becomes brown, and finally black, and as already stated, the whites again become perfectly clear. A short washing in water concludes the process.

The effect on the gradation, photometrically estimated, is fairly even, but the contrasts are slightly reduced.

T. THORNE BAKER.

THE REASON WHY.*

For many years the professional photographer has been made the target of criticism on account of the lack of art contained in his work as it is placed before the public. I am aware that much of this criticism is just, and that a portion of the fault is properly charged to the photographer, but many fail to consider for a moment that the public may be the greatest violators of the rules of art, and that the photographer must to a certain extent furnish his patrons exactly what each demands.

There are other reasons which enter into the existing conditions, such as the lack of opportunity on the part of the photographer to equip himself early in life with a thorough art education; but this is a small matter compared with that great obstacle—that of the public—which knows exactly what it wants and will have regardless of the advice of the photographer, and if it cannot be served at Smith's studio will transfer its patronage to Jones's, where it can be served if it will pay the price.

I think that it will be generally conceded that the great mass of professional photographers can produce far more artistic work than is now produced if they only had the opportunity. I do not think that any large number of progressive workers of the craft are satisfied with the work they are now producing. It is only fair to the profession to make the assertion that they know that it is contrary to good art, good taste, and the general fitness of things to produce work in which an equal emphasis of light and distinctness is given to all parts of the drapery that should be alone concentrated on the face; that we all know that the face of the model is the important consideration and the draperies secondary and immaterial matters, but when we attempt to make this matter plain to our patrons, especially to women with pretty gowns, and men

who belong to the class of good dressers, we find that to them clothes are weighty considerations, and that the photographer who can best picture with all possible detail the attractiveness of the costume is the one who best fulfils their ideas of art.

It is fair to remember in this connection that the photographer, like the merchant, must sell his wares or close his doors. Rent must be paid; stockdealers' bills must be met, weekly salaries promptly forthcoming, and to do this we must satisfy our patrons and give them what they demand, if we cannot induce them to order what is best.

I am sure that my brothers in the profession would be only too glad to escape from the drudgery of excessive retouching and the almost universal use of the etching-knife in working up the negatives, but, until there is a radical change in the public taste, it seems as though we are chained to the task which we ourselves are in a large degree responsible for in our attempts to please our patrons.

In this connection I have one suggestion to make, and in time it may prove a path of escape. Let each operator, when making a sitting, make a portion of his negatives to illustrate his own ideas of the best work that he can do in the arrangement, lighting, exposure and development, and in submitting proofs be ready, if asked for an opinion, to explain intelligently to his patron why the negatives made in accordance with well-recognised principles of art are the best, but at the same time convey the idea that you are there for the purpose of furnishing what the patron may demand.

Some day there will come to your studio a person who is discerning enough to understand that a portrait is something more than a carefully tabulated inventory of wearing apparel, and you will get an order for some of the work that the masses would reject. It will be a starting in the right direction; and as these orders are repeated

* From "Wilson's Magazine."

the opportunity of displaying in your show-case the portraits of distinguished persons who are willing to accept portraits which show their personality, rather than display their handsome gowns, will have a wonderful influence with the masses, who are ever ready to follow the leader, and the result will be a better art in your work, and an occupation which is more congenial than the catering to a popular demand which is largely in the wrong direction.

G. V. BUCK.

Exhibitions.

CAMBRIDGE PHOTOGRAPHIC SOCIETY.

This exhibition was opened on Tuesday of last week by Sir Robert Ball, at the Guildhall, Cambridge. The judges, Messrs. A. Horsley Hinton and H. Snowden Ward, made the following awards:—

MEMBERS' CLASSES.

Architecture.—Plaques: Rev. H. R. Campion, Ely; D. J. Scott. Hon. mention: Morris S. Heycock and W. H. Hayles. Figure studies.—Plaques: D. J. Scott and Morris S. Heycock. Hon. mention: W. C. Squires. Landscapes, etc.—Plaques: J. Johnson and A. Barrett. Hon. mention: Miss G. J. Robson and W. C. Squires. Still life, etc.—Plaques: W. Farren and H. W. Chapman. Hon. mention: Miss D. M. Sandford and W. H. Hayles. Lantern slides.—Plaques: W. C. Squires ("Youth and Age") and W. Farren ("Flying Gannets"). Hon. mention: Dr. F. J. Allen ("Croscombe") and W. H. Hayles ("Pigs' Flea"). Record and survey.—Plaques: D. J. Scott and W. H. Hayles. Hon. mention: W. H. Hayles.—Silver plaques for best picture in the members' classes: D. J. Scott.

OPEN CLASSES.

Architecture.—Plaques: W. A. Clark, Moseley; and S. G. Kimber, Southampton. Hon. mention: J. W. Johnson, Kettering. Figure studies: Miss N. Hyde, Worcester; and Arthur Marshall, Nottingham. Hon. mention: Dr. J. H. Wilson, Colchester; A. Gordon Smith, Bewdley; Dan. Dunlop, Motherwell; and Miss Enid T. Brailsford, Bradford. Landscape.—Plaques: Basil Schön, Bedford; and Arthur Marshall. Hon. mention: E. B. Wain, Norton-in-the-Moors, Staffs.; and F. Judge, Hastings. Still life.—Plaques: H. W. Chapman, Cambridge; and E. C. Seymour, Watford. Hon. mention: W. Farren, Cambridge; and A. S. Cane, Cambridge. Lantern slides.—Plaques: F. Judge ("October") and F. Tryhorn, Liverpool ("A. Norman Arch"). Hon. mention: J. Ludlam, Leicester ("Winter") and Dr. G. H. Rodman, East Sheen, S.W. ("Pollen of Hollyhock"). Silver plaque for best picture in open classes: Arthur Marshall.

KODAK PICTURES AT THE STRAND GALLERY.

An exhibition of photographs by distinguished Kodak users is now open at 40, Strand, London, and the personality of the photographers is proving as attractive to the visitors as the artistic merits of the pictures themselves. No less than 320 prints are on view, and they testify amply to the extent to which the Kodak is employed by persons of rank. The catalogue bristles with the names of lords and ladies, while a collection of "Royal" Kodak pictures by H.M. the Queen and H.R.H. Princess Victoria are, needless to say, given special prominence. These are good, both technically and pictorially, and in most instances are, of course, unique as regards point of view. Among the portraits is an excellent one of Lord Kelvin, taken by Lady Kelvin, and a characteristic picture of the Earl of Clanwilliam, in full Admiral's dress, by

Lady Beatrice Meade. A number of photographs of archaeological and historical interest, by the Duchess of Manchester, are on view, and of special interest, in connection with the recent war, are the photographs of sunken vessels at the entrance of Port Arthur. Portraits of General Oyama, General Ian Hamilton, and General Kodama, and General Kuropatkin and staff, taken by Sir A. B. Hepburn, pictures by Prince Khilkoff show Lake Baikal and the difficulties of transport there during the late campaign. Among others whose photographs have been secured by Kodaks are Sir Norman and Lady Lockyer, Lady Playfair, Duc d'Orleans, Lady Castlereagh, Sir Frederick Treves, Lady Sarah Wilson, Duchess of Westminster, Dowager Countess of Aylesford, and Lord and Lady Rathdonnell. Altogether the exhibition is one of exceptional interest, and well worthy of a visit.

HACKNEY PHOTOGRAPHIC SOCIETY.

THE seventeenth annual exhibition of the Hackney Photographic Society was opened at the Hackney Baths, N.E., on Wednesday, November 1. The show compares very favourably with its predecessors in point of size, and the inclusion of a great number of works collected from the R.P.S. Exhibition and Salon point to its importance and popularity. Both the open and members' classes were well supported, and no less than 518 pictures were on view. Visitors were well catered for. Attractive stalls of trade exhibits were displayed by: The Adhesive Dry Mounting Co., Ltd., of 27 and 28, Fetter Lane, E.C.; R. and J. Beck, Ltd., of 68, Cornhill, E.C.; Burroughs, Wellcome, and Co., of Snow Hill, E.C.; F. W. Dadd of 192 Mare Street Hackney; Edmunds and Co. of 3, Extra Buildings, Columbia Road, N.E.; C. P. Goerz, of 1-6, Holborn Circus, E.C.; Houghtons Ltd., of 88 and 89, High Holborn, W.C.; T. Illingworth and Co., of Willesden Junction, N.W.; Kodak, Ltd., of Clerkenwell Road, E.C.; Photographic Materials Co., of Rickmansworth; Rawlings and Co., of 406, Mare Street, N.E.; E. F. Stack, of Leyton, Essex; and Wellington and Ward, of Elstree, Herts; and, in addition, instrumental concerts and lantern lectures were given each evening. The judges, Messrs. Reginald, Craigie, A. Horsley Hinton, and Rev. F. C. Lambert, made the following awards:—

Open Classes.—Best Picture in Open Classes: Silver plaque, J. E. Latham. Class G—Portraiture and Figure Studies: Bronze plaques, Miss M. Silverston, Arthur Marshall. Class H—Landscape, Seascape, and River Subjects: Bronze plaques, E. W. Taylor, W. A. I. Hensler. Class I—Architecture: Bronze plaques, R. Summerford, H. W. Bennett. Class J—Animals, etc.: Bronze plaques, E. Seymour, D. W. Kyle. Class K—Stereoscopic: Bronze plaques, H. Wormleighton, F. G. Tryhorn. Class L—Lantern Slides: Bronze plaques, W. A. I. Hensler, E. R. Bull.

Members' Classes.—Best Picture in Members' Classes: Silver plaque, H. W. Lane. Class A—Portraiture and Figure Studies: Bronze plaques, W. A. I. Hensler, J. O. Grant. Class B—Landscape, Seascape, and River Subjects: Bronze plaques, W. H. Fowkes, W. A. I. Hensler; certificate, J. J. Westcott; medal, W. Selfe; certificate, W. J. Chandler. Class C—Architecture: Bronze plaques, S. C. Stean, F. E. Roofs. Class D—Animals, Still Life, etc.: Bronze plaques (2), A. D. Fort; certificate, W. Selfe. Class E—For Pictures of any Subject, etc.—Bronze plaques: G. Topple, A. C. Fort; certificate, A. Hyder. Class F—Lantern Slides: Bronze plaques, W. Selfe, W. A. I. Hensler; certificates, A. J. Linford, W. Selfe.

Trade Section.—Best Display: Silver medal, Messrs. Houghtons Ltd. Most Useful Photographic Novelty: Silver medal, Kodak, Ltd., for "The Premo Reflex Camera."

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents were made between October 25 and 26:—

CINEMATOGRAPHS.—No. 21,476. Improvements in cinematographic cameras and projectors. Ernest Osman Brown, 9, Queen's Road, Bournemouth.

CAMERAS.—No. 21,909. Improvements in photographic cameras. Wilhelm Salow, 111, Hatton Garden, London, E.C.

COLOUR EFFECTS.—No. 21,913. New method of mounting portraits and artistic reproductions generally, particularly photographic, to produce luminous reflections and diaphanous, transparent and brilliant colour effects. Fernand Paul Georges de Neuville, 72, Cannon Street, London, E.C.

SHUTTER.—No. 21,950. Shutter or screen for photographic cameras. William Boyd Henderson, 108, Westbourne Grove, London, W.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

DAYLIGHT CARTRIDGES.—No. 3,474, 1904. The invention is to obviate set-off of numbers and markings from the wrapping paper, and at the same time preserve the general appearance and manner of using the well known cartridges. This is effected by making the covering paper wider than the sensitised film, and locating the indicating and severing markings upon the extending edge of this opaque paper or backing, so that they will not come into contact with the film when the cartridge is wound into a roll. Kodak, Limited, 57-61, Clerkenwell Road, London, E.C.

TELEPHOTO LANTERN LENS.—No. 23,888, 1904. The application of the telephoto principle to a projection lens is thus described in the specification:—Use is made of a positive lens which consists of two or more separated elements, each of which elements may consist of one or more lenses connected together. Between the positive lens and the lantern slide is placed a negative lens, consisting preferably of two lenses cemented together. An adjustment is provided by which the distance of the negative lens from the positive may be varied. The complete lens thus made has a variable focal length according to distance between the negative and positive portions thereof, as, for instance, from 9 in. to 20 in. equivalent focus. It has this further advantage that the distance of the lens itself from the lantern slide is much less than its equivalent focus, and consequently a smaller lantern can be used than would otherwise be the case. The lens is so made that the negative part can be removed and the positive portion used alone as a well corrected lantern lens of shorter focus. Whereas different forms of positive lenses may be employed, the negative lens should preferably have a diameter giving a clear aperture of not less than the focus of the positive lens divided by $3\frac{1}{2}$, and it should preferably have a negative focus of not less than 9-12ths that of the focus of the positive lens. The following is stated as a satisfactory method of making the negative elements. A double concave lens and a concavo-convex lens, one surface of the concave lens being the same curve as that of the convex curve of the concavo-convex lens, are cemented together at this so-called contact curve. The curves of these lenses are so placed that the radius of curvature of the surface which is nearest the lantern slide is approximately in the ratio of 3, that of the contact curve 2, and that of the surface nearest the positive lens 6, the double concave lens being nearer to the lantern

slide than the concavo-convex. Conrad Beck, 68, Cornhill, London, E.C.

CINEMATOGRAPH PICTURES.—No. 21,540, 1904. The patent is for obtaining the effect of animated photographs by the rapid transposition of sheets or plates bearing pictures, or, of mirrors, or reflecting surfaces, mounted upon a binding band and operating positively and successively. Jules Hippolyte Cortes, 15, Francis Street, Tottenham Court Road, London, and Paul Frederick Boehringer, 54, Charleville Road, West Kensington, London, W.

New Material.

"Circoid" Developers and Toners. Sold by Houghtons Ltd., 88-89, High Holborn, London, W.C.

With the establishment in popularity of the ready-made developer or toning bath manufactured in the dry state and needing only solution in water, Messrs. Houghtons, Limited, can feel confident of issuing a series of compressed chemicals in tablet form. "Circoids" will be certain to find numbers of photographers wedded to the time-saving system of the tablet, and, presuming that they are excellent in themselves, they may be recommended as the *ne plus ultra* of convenience. And it is therefore incumbent on us to say that after putting the "Circoids" submitted to us to the test of use, we found them easily soluble and photographically active in their respective applications. We write thus of the pyro-soda and metol-hydroquinone developers and of the combined bath. "Circoids" are sold at a uniform price of 1s. per box, for which sum one can prepare 40 oz. of developer or 20 oz. of tone-fixing solution. In the case of developers, Messrs. Houghtons are making a practice of giving the Watkins factor on the circular of instructions. The hydroquinone has a factor of 9, pyro-soda of 8, and metol-hydroquinone of 16.

CATALOGUES AND TRADE NOTICES.

COLOURED slides of natural history subjects are a new and cheap line with Messrs. W. Butcher and Sons, Camera House, Farringdon Avenue, London, E.C. The slides, coloured, are put up in sets of eight at 2s., and there are some twenty sets to select from.

AN abridged catalogue of lanterns and lantern apparatus has been sent us from J. Lizars, 101 and 102, Buchanan Street, Glasgow. This catalogue contains practically everything necessary for the projection of lantern slides. Mr. Lizars has over 250,000 slides in stock for hiring purposes, and a full catalogue of 250 pages, containing all information, will be sent on receipt of 6d.

THE "Aptus" winter specialties are briefly described in a catalogue just to hand from Messrs. Sharp and Hitchmough, 101 and 103, Dale Street, Liverpool; particulars of enlargers, screens, lenses, lanterns, lamps, condensers, illuminants, etc., are included. A copy will be sent free on application.

For the sake of more precise description, Messrs. John J. Griffin and Sons have renamed the various brands of Velox paper, and at the same time have reduced the prices of several varieties. This series of paper is now divided into "Vigorous," for weak negatives, "Soft" for strong negatives, and "Special," for papers of distinctive matt surface. The worker has thus no legitimate grumble that his Velox is not what his taste desires and his negative demands, although the dealer may not look upon a multiplicity of brands as an unmixed blessing.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Nov.	Name of Society.	Subject.
10	Aberdeen Amat. Photo. Assn.	"A Trip to St. Kilda" (Federation Slides) Mr. T. Lupton.
10	Colne Camera Club	"Carbon." Demonstrated. Mr. R. T. Lawson.
10	Leicester Lit. and Philo. Society	"Platotype Printing." Demonstrated. Mr. R. E. Woolmer. <i>Amateur Photographer Prize Lantern Slides</i> , 1905.
10	Barrow Naturalists' Field Club	"The System of the Stars." Illustrated. Variable Stars. Rev. T. E. R. Phillips, M.A.
13	South London Photo. Society	"Lantern Slide Making." Mr. W. Page.
13	Luton Camera Club	Practical Evening on "Auto-Pastel." Organised by Messrs. Staddon and Baker.
13	Southampton Camera Club	"Morocco." Illustrated. Mr. J. H. Avery.
13	Leek and District Photo. Soc.	Exhibition of Members' Prints.
13	Dewsbury Photo. Society	General Discussion on Photographic Matters.
13	Wallasey Amat. Photo. Soc.	Lantern Lecture, "Beautiful Mona."
13	Halifax Camera Club	"Places and People in Westmorland." Mr. Percy Lund.
13	Glasgow Eastern A.P.A.	Annual Exhibition—Last Date for Entries.
13	Sunderland Camera Club	"A Holiday in Algiers, Tunis and Sicily." Illustrated by Lantern Slides. Mr. T. Walton.
13	Oxford Camera Club	Exhibition of the Royal Photographic Society's Prize Slides.
14	Royal Photographic Soc.	"Application of Photography to Investigations of Natural Science." F. Martin Duncan.
14	Worthing Camera Club	1. "Composition and Selection of Pictorial Subjects." Illustrated. Mr. Arthur C. Osborn. 2. "Italy in an Hour." Illustrated by Miss Woodward. Lecture illustrated (any subject).
14	Glasgow Southern Photo. Assn.	"Natural History Records with a Camera." Illustrated. Mr. G. A. Booth, F.L.S., M.B.O.U.
14	Birmingham Photo. Society	"Combination Printing." Mr. A. Poole.
14	St. Helens Camera Club	"Photographic Lens Making," with Samples of Lens Paris and Lantern Slide Illustrations. Mr. Harbottle.
14	Gateshead Camera Club	Rotary Co. Demonstration.
14	Hackney Photographic Society	Bromide Toning Competition. Members. Swaledale. Mr. R. Borrow.
14	Holmfrith Photographic Soc.	"Exposure and Development." Mr. J. W. Stanciliffe.
14	Darlington Camera Club	"A Holiday in Switzerland." Mr. James Emmott, R.O.
14	Otley & Dis. Cam. & Art. Soc.	"Velox and its Application." Messrs. John J. Griffin & Sons, Ltd.
14	Nelson Photographic Society	"Bromide Papers—Printing, Toning and Finishing." Mr. T. W. Brown.
11	Thornton Heath Photo. Soc.	"Three-Colour Photography." Rev. Johnson Barker.
14	Bristol Photographic Club	<i>Amateur Photographer Prize Slides.</i>
15	Worcestershire Camera Club	Judging of Prints and Slides taken on the Outings held during the summer.
15	Coventry Photo. Club	"Orthochromatic Photography." Mr. Arthur Payne, F.C.S., F.R.P.S.
15	G.E.R. Mechanics' Institution	"Old Leeds." Illustrated. Mr. Alf. Matkinson.

ROYAL PHOTOGRAPHIC SOCIETY.

TUESDAY, October 7. Mr. L. Clift in the chair. Mr. A. Brookman gave what was announced as a "practical demonstration" on "Copying." He dealt more particularly with the copying of oil paintings and black-and-white subjects, and laid it down as a rule that to obtain the best results a long extension camera and a long focus lens were necessary. A perfectly rigid camera of the square type was recommended, and the lecturer drew attention to the inadequate proportions of the modern tripod top. A tripod top equal in size to the baseboard of the camera was essential if perfect rigidity was desired. The tripod should be strong and firm, and to prevent slipping the three legs should be held in position by one of the several devices he showed. The first was a folding T-shaped piece of wood with a series of holes bored in it. The front leg of the tripod was placed in a hole in the tail of the T, and the other two in holes in the cross-piece. Another method was to employ three pieces of light metal shaped like the letter J. These were joined together at the top, so that they could move easily, and formed three grappling irons, which, engaging with the tripod legs, prevented them spreading apart. The third contrivance consisted of three slotted strips of metal, one of which was connected to each leg of the tripod, and all three firmly clamped in any position in the middle by means of a bolt and nut. This small piece of apparatus is already on the market. As regards the lens for copying, Mr. Brookman said there was no question as to the pre-eminence of the modern flat-field anastigmat for the purpose. A.R.R. or even a single lens might be used, but this necessitated such excessive stopping down to secure marginal definition that the exposures, especially when a colour screen was used, became prohibitive. Sharpness, to render every detail of the original, and freedom from fog were essentials for good copying work. To escape the latter, which frequently occurred with long exposures, from reflections inside the camera, it was always best to use a larger camera than was required for the plate employed. Marginal fog from reflected light from the rebate of the dark slide and back of bellows was thus avoided, and in any case better results were obtained if a cone of cardboard, blackened inside, was fitted over the lens to cut off all light except that coming from the picture. When copying a large painting it was necessary, in addition to using as long focus lens as possible so as to get a good distance away, that the camera should be placed pointing directly at the middle of the frame. Mr. Brookman's method of securing this was to use a piece of string, say 12 ft. long, with a drawing pin fastened to one end and a piece of chalk to the other. The pin was fixed to one corner of the frame, the string held taut, and an arc drawn on the floor with the piece of chalk, roughly, about opposite the middle of the picture. The string was then shortened to one-half by tying a loop and another arc drawn opposite the first. The drawing-pin was now transferred to the opposite corner of the frame, and two more arcs drawn on the floor bisecting the first two. The line drawn connecting these two points of intersection pointed at the exact centre of the frame, and on this line the front leg of the tripod should be placed with the lens pointing in the same direction. The two other legs should be placed on a line drawn at right angles to the first line. When copying dark pictures, the glass, if any, should, if possible, be removed. Otherwise a big black screen was necessary to avoid reflections. This should be used in front of camera, with a small hole for lens to peep through, and was another point in favour of long focus lenses. If a short focus lens was used with the screen, too much light would be cut off or the lighting would be uneven.

The ideal conditions for copying would be to use a vertical easel for the picture, and both easel and camera stand to run on small tram lines, so that they were always truly parallel to each other.

Sunlight was bad for copying purposes. A good diffused light gave best results, but the lecturer had employed the arc light and incandescent gas with good results, provided they were well placed and screened from the lens. One point Mr. Brookman insisted on, and that was never turn a picture upside down for copying, especially an oil painting, but always try and copy it in light coming from the same direction as that in which it was painted. The purpose of the artist who had probably considered the effect of each brush mark would be entirely defeated if the picture were copied in the wrong lighting. It was also a fact that an oil painting copied by light coming from the same direction as it was painted in could be more easily copied, as it showed the least "glare" under the circumstances.

Water-colour paintings generally required less exposure than oil paintings. A dark water-colour wanted about one-quarter the exposure of a dark oil painting, and when starting a long exposure it was wise to always note beforehand the time when to leave off, and write it down and stick to it. Always give as full an exposure as possible, and, in the case of black-and-white subjects, a small stop was necessary to avoid clogging of high lights. To examine the picture for glare, the only correct way was to remove the lens and ground glass after focussing, and then look through the camera from the position of the dark slide. To overcome excessive contrasts in copying pictures the lecturer used pieces of black velvet, which he attached by means of wafers to the high lights, such as the face, hands, collars, etc., after a certain exposure had been given, so as to allow the dark portions to "catch up" with a prolonged exposure. For black-and-white work he preferred using a slow photo-mechanical plate; for all colour work he advocated ortho plates, of course, and he preferred colour-sensitising ordinary plates himself in preference to buying them ready sensitised. The dyes he used were pinachrome and pinacyanol. He used the Ilford half-tone plate dyed with the latter for most work, the exposure being increased about three times. A screen was, of course, necessary. Pyro-soda was the developer for negatives, and metol-hydroquinone for transparencies.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—Ordinary meeting, November 2, Mr. A. Haddon in the chair. Mr. J. Burgess read a paper on the "History of Gelatine Emulsion Plates." He afterwards showed two specimens of colour photographs printed in two printings from an ordinary negative with a relief akin to that of the Woodbury process. The process was simple, and prints could be repeated without variations. Asked if there was not some hard work on the prints, he said there was, but it was easily detected, and only took some ten minutes. The prints were much admired, and members showed great eagerness for details. Mr. Burgess stated that he intends to publish a book on the subject.

GLASGOW ARCHITECTURAL ASSOCIATION.—A lecture was given at the last meeting of this Association by Mr. Robert F. Sherar, a delegate from the Edinburgh Association, on "Linear Perspective," illustrated by photography. The lecturer said that the researches of the science as such had been practically exhausted by Dr. Brook Taylor and successive writers in the eighteenth century, but it was always possible to improve on the methods of stating facts and of teaching how to apply the theory to practice. He thought that illustrating perspective as he did that night by photography would be something new. He then described the elementary conditions on which the science depended, and distinguished between the perspective appearance of objects as we see them and the perspective image as we draw them on paper. Two photographs of the same building from the same spot were shown, one on the right-hand side of the photographic plate and the other on the left-hand side, which were quite different in the perspective lines, and it was explained that they were both equally correct records of the perspective

appearance as we saw it, but records only. To prove this, Mr. Sherar exhibited a photograph of the first of these two "pictures" taken with the camera placed so that the image of the picture fell on the left-hand side of the photographic plate instead of the right-hand side, and the result was the same as the second picture. From this he laid down the rule that the perspective appearance of objects depended on the position of the spectator, or, in photography, on the lens, and on this only; and that the perspective image depended on the surface on which it was delineated, whether it was a picture plane, vertical or otherwise, or a picture curved, as a panorama, etc.

BOROUGH POLYTECHNIC PHOTOGRAPHIC SOCIETY.—On Wednesday, November 1, Mr. Ernest Human lectured before the members of this society upon "Combination Printing." He first of all pointed out that the method usually adopted of first making a rough print and then cutting along the horizon line to make two masks was, in any but expert hands, a delusion and a snare, because although the two masks should in theory exactly match and join up in the printing, it was seldom indeed that one did not obtain a series of black and white lines extending into the sky, the reason being the unequal stretching of the paper when damped to place in position upon the negatives. The method he adopted and used was that of, what he would term for want of a better name, "vignetting." To use the method successfully, one should employ larger size printing frames than the negatives in use, as, for instance, 12 x 10 frame for 1-1 plates, 10 x 8 for $\frac{1}{2}$ plates, and so on. In practice the frame was taken, a sheet of clear glass put in and the negative was placed on this so that the hinged back just caught the top of it by, say, some $1\frac{1}{2}$ in., if a whole plate, smaller negatives pro rata. Should it be

desired to extend the lengths of the print by adding extra sky, the extended end was protected by a sheet of opaque paper, the frame was then turned over and a sheet of cardboard with a turned-up edge was fixed into position, so that it covered the horizon line; the whole was then put out to print in the shade. The figure will make this all clear, A A being the frame, B the negative, C the extending protecting paper, D the vignette, and E the hinged back. By the use of the larger frame it was pointed out that extended skies could be easily obtained, foregrounds could be added, or a negative taken landscape way of the plate could often be made a better shaped picture by taking a little out of the middle, or it may be only one end, and by extending the sky making an upright picture of 10 to 11 in. by 7 or 8 in., this very often proving an improvement, both to shape and subject. Thus cattle which got into a picture could by this method of vignetting, be taken out and new grass or foreground put into their place by the simple aid of two printing as for the sky, using the vignette at the reverse end; this method was followed for all papers giving a visible or semi-visible image, for carbon and other papers of that class, marks were made upon the edge of the printing-frame, and the vignette used in the manner described.

For bromide the larger frame was still used, together with the marks, and a sheet of cardboard was carefully brought from the top or bottom of the frame to the horizon line, and then kept upon the move for from 1 to $1\frac{1}{2}$ in., with a to-and-fro movement. Using these methods, skies or foregrounds could be put into pictures. The lecturer then explained at some length the method employed for putting figures into landscapes by the aid of blocking-out and making two

transparencies, from which a new negative was made either the same or an enlarged size. For lantern slides he recommended that the slide be first made, and then used as a mask for making the cloud cover glass one had only then to bind the two together to obtain the finished slide.

WOOLWICH PHOTOGRAPHIC SOCIETY.—On October 26 Mr. J. Spiller, F.R.P.S., lectured before this Society on "Early Photographic Activities at Woolwich," in which nearly half a century ago he took a part. In 1837, when first appointed to the War Department, there were cameras in possession of the Arsenal authorities, particularly in the manufacturing departments, but no one was specially told off to use them. At this stage a course of instruction was initiated at the Royal Artillery Institution, followed by a second class held in 1862. Meanwhile the speaker held a three years' engagement as photographer to the Royal Military Repository, 1858-1861, attending one day a week, and with the help of a small band of "non-com." pupils succeeded in producing a series of gun drill pictures, war material and equipment, engineering operations in or about the Rotunda pond. More than a hundred large-size negatives were taken by the collodion process, printed as usual on albumenised paper and mounted on thin cards for issue to outlying stations. Then in 1860 Shoeburyness wanted records of shot practice against the "Warrior" bulwarks erected on the Essex marshes, so it was arranged to strengthen the local photographic resources and provide for printing from the negatives at Woolwich. By the year 1863 a central photographic establishment at Woolwich was formed under Sir Frederick Abel, the War Department chemist, with the assistance of Mr. Spiller and his already trained military staff, and an account of such proceedings was given at the December meeting of the Photographic Society of London.

WORCESTER CAMERA CLUB AND PHOTOGRAPHIC SOCIETY.—On Wednesday of last week Mr. F. Hornblow gave a demonstration on "Toning Bromide Prints" before the members of this society.

DEVONPORT CAMERA CLUB.—At the Technical Schools on Wednesday of last week the autumn session of the club was inaugurated with an address from the President, Mr. W. T. Treglohan, B.A., on "The Advantages of Photography," premising that there were many who were hesitating as to whether they would take up the work, and were asking themselves the pertinent question: "What shall I gain by it?" He would say, first, that in doing so they would learn the art of seeing. There was not the slightest doubt but that the student of photography soon discovered that he began to see more as he advanced in his experience. He discovered more keenly than before what were the lines of beauty in a scene and in things that were interesting to photograph. And so far as scenes were concerned this led to looking for the discovery of the best point of view. It would soon be borne in upon the learner that in photography it was charm of form rather than of colour that made the greatest impression. Attempts at getting a true rendering of the scene, with its beauty, as colour made it, were very disappointing. But none the less was it desirable to be able to see scenes that would translate into good photographs. In the practice of architectural photography, the training in seeing was most valuable, and enabled the observing photographer to discover greater charms and beauties than the ordinary tourist would do. And the influence of the scene, apart from photography, might be most beneficial and helpful. Photography, too, led to a love of the beautiful, which was a growing and increasing faculty; and in opposition to this was the distasteful work such as was too common in the topographical postcard. Those who favoured portraiture had great need of learning to see, and could not do better than study the best works of the leading portrait or figure painters of these and former days. Nothing was more disappointing in result than

figure work done without thought or care, and the longer the experience the better would the work be if it were thought out on the lines of experience and good taste.

EALING PHOTOGRAPHIC SOCIETY.—In his lecture on "Architectural Photography," which was well illustrated by lantern slides, Mr. H. Creighton Beckett recommended the use of long focus lenses—wide angle lenses should never be used if a long focus one would answer. For exterior work, he found the best results were gained when the subject was lit by weak sunlight, striking it at an angle of about 30 deg. For interior work full, even over-exposure, should be the rule, such exposure as will just render the detail in all but the least important shadows being what is required.

CROYDON CAMERA CLUB.—Mr. John H. Avery presented a triple lecture and demonstration here last week. First came the sulphide toning both for bromide prints, and a number of Messrs. Wellington and Ward's papers were toned a rich sepia. So good, in fact, were the results obtained that the somewhat strong nasal impressions received at the same time were disregarded by all present. The formula recommended for the papers in question is as follows:—A: Bromide of potash, 600 grains; ferricyanide of potash, 400 grains; water (to make) 10 oz. B: Sulphide of soda, *pure*, 1 oz.; water (to make) 10 oz. Take 1 oz. of A to 9 oz. of water, and $\frac{1}{2}$ oz. of B to $9\frac{1}{2}$ oz. of water. The prints are bleached in the former bath, rinsed, and placed in the latter, where they soon acquire a pleasing sepia colour. Prints bleach better, Mr. Avery said, when dried first, and they must be thoroughly freed from hypo. The next item on the programme consisted of the "Dry Mounting Process," and, by means of an inexpensive little machine, the lecturer successfully and most expeditiously mounted a large number of prints, on the thickest cardboard down to tissue paper, without the slightest cockling in any case, and in addition manufactured several plate-sunk mounts out of stiff paper. The third subject proved to be an exposition of the Scott's Studio "Bromide Paper Printing Machine" for art papers. In the discussion which followed on sulphide toning, Mr. H. P. C. Harpur said it was not obligatory to thoroughly free the prints from hypo before bleaching, and, being challenged upon the point, he tore a print into halves, and promptly adjourned to the dark room, placed one half in a strong solution of hypo for a few minutes, washed it for three minutes exactly, and returned. Much interest was evinced as to how the two halves would respectively bleach and tone, and it must be recorded no difference was discoverable. Mr. Avery said this was all very well, "One swallow did not make a summer," and he maintained care should be taken in the direction indicated by him.

At the Aberdeen Photo Art Club last week Mr. G. L. Smith, President, gave a lecture on "Art in Photography." Mr. Smith said in times past it had been common to speak of photography as the art science. He held that in photography itself there was no art, it was a science pure and simple, a difficult science, requiring a knowledge of many things, still a science. The photographer might have the best lens and camera procurable, he might have a thorough knowledge of the technics of his science, yet never be able to produce anything better than a very good photograph. The camera, and all the knowledge connected therewith, were simply the means by which a picture might be made, but unless the user of these had in him the spirit of the artist, and the power of artistic selection, it was vain to suppose that a picture in the true sense of the word would result. It was as natural to suppose that a painter, because possessed of brushes, canvas, and the finest colours, with a thorough knowledge of how to manipulate them, could therefore produce a picture of outstanding excellence. He contended that thorough knowledge in the technics of photography was in the first place essential, but beyond that, the art was in the mind of

the operator, and not in his camera. Could he make his results express some feeling, or thought, or emotion? If he could not he was simply a photographer and not an artist. The true painter could, in a manner, make his picture express the idea he wished to convey by taking away superfluous light and strengthening or suppressing shadow where desirable. The camera represented whatever was before it, and the only power of its user lay in the selection of that part which would best express the thought aimed at.

New Books.

"Photograms of the Year, 1905." London: Dawbarn and Ward, Limited. 2s.

"Give us Art" is the cry of the two contributors who are the first to appear in Mr. Snowden Ward's annual review of pictorial photography. Herr Loescher, speaking for Germany, sees photography passing through a period of imitation art, the "art" which is an external copy of the real thing. M. Demachy writes to the same effect in diagnosing the dead level of pictorial photography. The photographic methods—gum, multiple-gum, and glycerine platinotype—have been out long enough for the seekers after sensation to have exhausted their possibilities. Hence no more seven-days' wonders in the exhibitions, but progress of a kind, M. Demachy thinks, which is towards beautiful lines and quality of colour. It is almost a source of perturbation to us to find M. Demachy and ourselves in agreement on modern tendencies in pictorial photography, yet his implication seems to be that the rapid progress of the last few years has been of a technical kind—in the acquisition of deftness in the methods just mentioned—and that now the movement forward is towards education in art is necessarily painfully slow, and of a kind to be unnoticed by the casual observer. We shall be glad to find M. Demachy right. Our protests in the past against the hectic way in which photographic processes were applied have been frequently expressed. Having allowed practice to run riot in producing things which were not great or good, but only novel or startling, "pictorial photographers" have reason to see happy auguries for the future in the present lack of "tours de force" and works which obtain notoriety.

But our chief concern is with the illustrative, not the literary portion of "Photograms of the Year," and first we would return thanks for the limit which the compilers have set on the catholicity of selection. One finds very few reproductions of a kind to bring photography into ridicule. There is rather more ordinary work than need be, and there are signs of the compilers' desire to associate work of a certain kind with certain workers—witness Van Jan's seascape with the inevitable nude woman—but, for the most part, the volume represents sane, creditable photography, and a study of its pages is a better introduction to current accomplishments than any exhibition.

Portraiture has a large share in the pages, and a professional photographer must be more obtuse than we conceive possible, if he fails to profit from the reproduced work of W. Crooke, William Gill, Speaight, Henry Spink, Miss Warburton, Ralph W. Robinson, Frederick Hollyer, H. A. V. Coles, A. L. Coburn, J. Craig Annan, and Furley Lewis, and from the Germans and Americans, whose work is almost wholly portraiture. And what a suggestion for a window picture is Louis Dick's study on page 45! We signalise the portraiture as of supreme interest to our readers, but the pictorial harvest of landscape and the like is equally gathered between the covers. In fact, the volume embodies its editors' aim to make it "an incentive and an inspiration to every lover of photography." Having in mind that the printing of some issues of "Photograms"

has invited criticism, we ought to add that the present volume is a beautiful production: the non-photographic person will probably prize it as a book for presentation.

"The Photographic Studio and What to Do in It." By H. P. Robinson. Iliffe and Sons, Limited. Price 2s. 6d. Third edition.

Revised by W. Robinson.

Whatever methods and means a newer school of portrait photographers may have discovered for the achievement of successful work, there can be no doubt that the broad principles laid down by the late H. P. Robinson in the first edition of "The Studio and What to Do in It," are still the best to-day. The present edition is the third, and Ralph W. Robinson, himself one of our leading professional photographers, who has undertaken its revision, says in the preface:—"I have found nothing of importance to alter. On the other hand, returning to a careful perusal of the book after twenty years everyday practice in portraiture, I find every point teachable in the art treated in the straightforward and practicable way characteristic of the author." The problems before the professional portraitist to-day are the same as they were when the first edition of the work appeared. Posing and lighting of the sitter, indoor and outdoor single figures and groups, and backgrounds, etc., are matters which are unaffected by improvements in processes and materials, and the advice and instruction given on these subjects and many others are as forcible and to the point now as when the first edition appeared. Beyond the old-time costumes in some of the original illustrations which have been retained, there is therefore nothing to indicate that the book has not been written during the past year. The amateur photographer who does not possess a studio will also derive much instruction from its pages, but to the professional who desires to make the most of the light and space at his disposal, the book should specially appeal.

"Pictures from Nature" is the title of a portfolio of fifteen photogravures made from photographs by Richard and Cherry Kearton. The size of each plate is 15 by 11, and they are very fine reproductions of some of the most popular pictures by these eminent naturalist-photographers. Messrs. Cassell and Co., Limited, are responsible for the production of the portfolio, and all who are interested in Nature, photography, art, or sport, should write to them for full particulars. The price is 10s. 6d., and the publishers have made arrangements with Messrs. Kearton for an edition de luxe, limited to one hundred numbered copies, wherein every picture will be autographed by the brother who secured the photograph. The price of this edition will be two guineas.

Part III. of the "I Go A-walking" Series of Nature books, illustrated by photographs, by Charles Reid, of Wishaw, has been issued. The present number deals with stream and lake side pictures. It is published by T. N. Foulis, 3, Frederick Street, Edinburgh, and is cheap at 6d.

BORDER Occasionally Seen Between Light and Dark Regions on Photographic Prints.—Professor Oliver Lodge writes to "Nature": I have once or twice been asked why photographs are apt to show a line or band or edging along the boundary of a bright and dark region. My assistant, Mr. E. E. Robinson, has thought of the reason, and it may be convenient to publish it. In a developed film the exposed portion perceptibly differs in thickness from the unacted-on portion, and accordingly the linear boundary of two contrasted regions may sometimes act as a cylindrical lens, and during printing either concentrate or disperse the light on the positive immediately beneath it.

THE Aerograph Co., Ltd., after some years' establishment at Memorial Hall Buildings, has removed to new offices at 43, Holborn Viaduct, London, E.C.

News and Notes.

THE NEXT R.P.S. HOUSE EXHIBITION.—A house exhibition will be opened on Friday, 24th inst., at 66, Russell Square. A departure has been made in this instance from the usual one-man shows, inasmuch the exhibition will consist of a selection of the works of the members of the Postal Camera Club. This club is one of the best and strongest of its kind in the country, and the pictures will be remarkable for variety and style. The club was until recently under the secretaryship of Mr. W. R. Bland. His mantle of office has now descended upon Mr. J. C. Warburg, who will formally open the exhibition on Friday fortnight. The press view will be on Saturday, 25th, from 11 to 3, and the private view on the same day from 3 to 6. The exhibition will then remain open until the New Year. Admission by presentation of visiting card.

R.P.S. LECTURE.—The lecture announced for next Tuesday at the Royal Photographic Society, 66, Russell Square, is "The Application of Photography to Investigations of Natural Science," by F. Martin Duncan.

PHOTOGRAPHY at the Society of Arts.—Among the sessional arrangements for lectures at the Society of Arts are several lectures of direct photographic interest. On November 22, Mr. Martin Duncan lectures on "The Cinematograph and its Applications," and a month later, on December 20, Mr. Charles W. Burdick is to discourse on "The Aerograph Method of Distributing Colour." Of the Cantor lectures, which are a feature at the Society of Arts, those on "Fire Risks" and "Fire Extinction," by Professor Vivian B. Lewes, are not without their interest to photographers and the photographic trade. A circular issued from the Society at John Street, Adelphi, London, W.C., will inform the recipient of the other activities of the Society and of the terms of membership.

KOHINOOR Paper.—Inquirers, other than the one who recently addressed us, may be glad to know that this paper—the manufacture of Roland Risse Flörsheim, Germany—is supplied by R. L. Hart, 7, Horsefair Street, Leicester.

PHILIP G. HUNT, of Manchester, notifies us that he has opened at 34, Paternoster Row, a London office for export and colonial business in photographic printing and publishing. Inquiries for samples and prices are invited from the wholesale trade, and will be answered to any part of the world.

ROYAL INSTITUTION.—Professor Herbert Hall Turner, D.Sc., F.R.S., is announced to deliver a Christmas course of lectures on "Astronomy," adapted to a juvenile auditory. The dates of the lectures are December 28 and 30, 1905, January 2, 4, 6, and 9, 1906, at three o'clock.

From a programme of the Croydon Camera Club's Exhibition, which is now open, we see that, apart from the exhibits, many other attractions are offered. To-night Mr. E. A. Salt lectures on "Three-Colour Photography," with special reference to Messrs. Sanger-Shepherd's system. A musical melangé is fixed for tomorrow. On Monday a cinematograph display is to be given by Mr. F. A. Delcomyn. Tuesday is filled with a lecture by Mr. C. R. Stockwell, entitled "A Trip to St. Petersburg and Moscow." On Wednesday (the closing night) Mr. F. J. Mortimer furnishes an illustrated lantern lecture on "Wave Formations" and "Marine Photography." In addition to the foregoing, the Platinotype Company's portrait lamp will work each evening under the direction of Mr. Salt. Its inventor—Mr. W. H. Smith, the President of the club—has evolved a new method of utilising the powerful illuminant employed. Only reflected light is allowed to fall on the sitter, the amount and direction of which can be varied at will. Mr. Smith is also responsible for a series of practical demonstrations on the platinotype, and Mr. J. M. Sellors for expositions of the carbon, or autotype process. The exhibition is held at Horniman's Hall, North End, Croydon, which is easily accessible from either West or East Croydon Stations. We wish its Hon. Secretary, Mr. W. H. Rogers, and all concerned, every success.

DEATH OF W. H. WALMSLEY.—We regret to record the death of Mr. W. H. Walmsley, of Philadelphia, on October 22, after an illness of only one day. The deceased gentleman was well known in photographic circles, and among other literary labours, had written a manual of photo-micrography. His sudden death comes as a painful surprise to ourselves, for little more than a week ago we received from him an article for the forthcoming "Almanac," to which for many years he had been a contributor.

Correspondence.

* * *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

* * *We do not undertake responsibility for the opinions expressed by our correspondents*

WHENCE COMES THE WORD "PHOTOGRAPH"?

To the Editors.

Gentlemen,—In reference to the first use of the word "photography," I have been making investigations myself, on Dr. Murray's suggestion. The utmost I can say is that I have found no trace myself in any printed matter of an actual earlier use of the word than that in the printed abstract of Sir John's paper, which for other reasons was not actually read to the Royal Society in March, 1839.

That does not justify, nor indeed go so far as to suggest even, that Sir John coined the word. But it is quite a simple idea to suppose that a man of his stamp would use the word almost instinctively, in distinction from the narrower French term, *heliography*. Light, as such, was Sir John's ideal study in physics, and I can well imagine how, when the need for a word sprang up in his mind, he would be the first to attribute the work of light to light, rather than to any luminary that sent it forth.

But adhuc sub judice lis est—though, so far ex parte—Dr. Murray's impartial hypothesis.—Yours faithfully,

W. J. HRSCHHEL.

92, Woodstock Road, Oxford, November 3, 1905.

To the Editors.

Gentlemen,—The only possible answer to Dr. Murray's question may perhaps be that the origin of the word is not known, and cannot now be ascertained. My own impression is that it probably came from France about the same time as the news of Daguerre's discovery. The word "photography" differs but slightly from "heliography," the original name used by Niepce, which would not be likely to be retained, considering the improvements that had been effected in the art and the probable desire to mark it as quite distinct from Niepce's process.

Dr. Murray says that his French friends have failed to trace the French equivalent of the word "photography" before 1839; but that is exactly what one would expect. Photographic processes were in existence before that date, but they did not attract attention. I suppose that very few persons had heard of "heliography" before they heard of "photography." The year 1839 was a year of photographic revelation; great interest was excited, and such a word as "photography" would then take root.

Dr. Murray suggests that Sir John Herschel may, "in the experiments that he had made for several years," have "invented the name photography for his own private use"; but Herschel had not been experimenting in photography for any length of time. I am unable at the moment to verify the date, but I am under the impression that it was in January, 1839, that Herschel first began to experiment in photography, owing to his having heard the rumour of what had been done in Paris. At that time he was unaware that anything had been done in England.

If, on the occasion of reading his paper to the Royal Society (March 14, 1839), he had supposed himself to be using in public, for the first time, a word familiar to himself but not likely to be familiar to his audience, he would probably have called attention to the fact. Even if he had not done so, his friends, and men of science generally, could hardly have failed to notice it, and it would

not have been forgotten just as the fact that he was the first to use the terms "positive" and "negative" in photography, has never been overlooked.

The point which you notice under the heading, "Ex Cathedra," that in the "Athenæum," from 1839 to 1843, the word "photography" is used in connection with Herschel's work only is certainly curious; but those persons who were principally interested in perfecting processes, to which they had given distinctive names, would, at first, find those names sufficient for their own use. Herschel, on the other hand, appears to have experimented more generally over the whole photographic field and would be likely to realise sooner the advantage of using a comprehensive term that had not come to be identified with any particular process.—Yours faithfully,

C. H. TALBOT.

Lacock Abbey, Chippenham.

November 6, 1905.

THE RESTORATION OF DAGUERREOTYPES.

To the Editors.

Gentlemen,—I should like to supplement your article on the restoration of Daguerreotypes by a few practical notes representing the result of personal experience.

Methylated spirit must not be used for the preliminary operation, either rectified spirit or absolute alcohol should be employed. Very little is required, so cost is not a matter of moment.

After the first washing with water, immersion for ten minutes in a fresh hypo fixing bath (4 oz. to the pint) will greatly facilitate the after cleansing operation with cyanide. The tarnish is partly removed by the hypo, and thus less work is left for the cyanide, and though little apparent effect may be produced, I have found that the cyanide invariably acts more rapidly after the hypo bath. The plate should, of course, be washed before the cyanide is applied. Though cyanide varies in strength, it seems to me to be safest to make a solution of ten grains to the ounce, and use that throughout. This prevents the accidental use of too strong a solution; while a ten grain solution I find to be quite effective even in the worst cases. The same solution should not be used too long. I find it best to use fresh solution every two or three minutes.

If the tarnish is very strong, you must not expect it to completely disappear in the cyanide bath. In very bad cases a kind of scar is left, that only disappears when the plate is dried. This mark will again reappear if the plate is again wetted; but it should be quite invisible in the dry image. For sealing I prefer a strong gelatine mountant and thin hard paper. When the binding is dry, I rebind with a second series of strips of the same paper, and then size the binding with gelatine. When this second binding is dry, two or three coats of celluloid varnish are applied.

The picture should be sealed directly after the cleansing operation, as, if left exposed, even for a short time, it becomes slightly dulled. The work must not be done in a laboratory or any place where chemical fumes are about. Chlorine fumes, for example, will speedily destroy the image.

As regards the delicacy of the image and the readiness with which it is removed by rubbing, I am not sure that this is not sometimes exaggerated. I have recently had to deal with some old Daguerreotypes that had been unmounted for years, and had been much handled and knocked about. They were, of course, badly scratched and terribly stained; but the removal of the stains showed that the images were intact. They were chipped in a few places, and salts had formed on the exposed copper, but only in these spots had the image actually disappeared. Scratches are very readily produced by the softest brush or wood pad, hence no attempt should be made to remove anything by friction. A particle of dust may, however, be picked up on the point of a damp brush without causing damage.

My experiences have been confined to untuned images, and with these I have found that cleansing is a perfectly safe and easy operation if reasonable care is taken. I do not think I have ever met with a toned or "gilded" image, and if Messrs. Kent and Lacey would kindly give us some information with regard to such images and their treatment, I, for one, should be very grateful. I imagine that the gold would be removed by the cyanide bath; but does this necessarily involve the "total destruction" of the image? Is retoning possible?—Yours, etc.,

C. WELBORNE PIPER.

46, Shooters' Hill Road, Blackheath, London, S.E.,

November 4, 1905.

To the Editors.

Gentlemen,—Allow me to add my mite on the subject. There are one or two points in your instructions that might be improved.

Alcohol is unnecessary, and in the hands of inexperienced operators may fail. I have in my mind a failure in the hands of my operator; it arose by his flooding the Daguerreotype with methylated alcohol; this precipitated a resinous deposit which I could not remove. My *modus operandi* is as follows:—I place the plate in a strong solution of cyanide potassium (unused) for a few seconds only, or sufficiently long to remove the tarnish; if left a long time in the solution the cyanide will attack the silver too deeply and remove the whole image. All that is now required is to well wash the plate in plain water, and finish with distilled. The plate should then be placed end up on a clean piece of bibulous paper, and allowed to dry spontaneously. If artificial means are employed, there is a danger of markings from a stoppage in drying. Latterly I used to cover the Daguerreotype with a protective coating to prevent further tarnishing. The varnish was composed of bees' or paraffin wax, 2 grains, benzole, 1 oz., carefully filtered. I am pleased to hear that Mr. Kent is still alive. We have other veterans in our midst Mr. Werge for one. I have not heard of the death of Mr. Richard Beard; he and Mr. Claudet were early in the field. Some years ago I amalgamated Mr. Beard's business with my own in King William Street, and I have had the honour of cleaning Daguerreotypes for him. I possess some thousands of his negatives (wet collodion). He personally retired in the fifties.—I remain, Sirs, yours truly,

A. L. HENDERSON.

Smedley's Hydropathic Establishment, Matlock,

November 4, 1905.

THE PERMANENCY OF MATT COLLODION PAPER.

To the Editors.

Gentlemen,—The letters on the permanence of collodio chloride prints have opened a discussion on a most important subject, and, perhaps, my own experience may be useful to others.

It is some years now since I used C.C. paper for ordinary single gold or platinum toning; but I found when using it that the prints toned with alkaline gold were remarkably permanent, and bore exposure to sunshine and damp in show cases in a manner quite surprising. In fact, they kept in better condition, under the same circumstances, than prints on platinum paper. Occasionally prints would be spoilt by pale yellow spots, which appeared only after they had lain all night in blotting paper. The blotters were sold as chemically pure, and the spots did not appear until the blotting paper had been in use for some little time. But I was never able to find out whether the spots were caused by some fungoid growths, such as mould, or mildew, in the paper; or whether chemicals were carried into the blotters by the wet prints. The spots never appeared when fresh blotters were used, and, as soon as a single

spot appeared the sheets were discarded. If a print, having the smallest spot escaped detection and was mounted, in a couple of days the spots increased and almost covered the print. I suspected hypo was the cause; but, as the prints were toned, fixed, and washed on the top floor, were drained on a sheet of glass, and then carried down stairs to a room where no hypo was ever used, or even taken into, I could never trace the cause of the trouble. The silver image was bleached to a pale yellow wherever the spots appeared. I never discovered a spotless print go wrong after mounting.

C.C. paper toned with the single bath is, I think, very fugitive; in fact, I believe all silver prints toned in an acid bath of any kind are impermanent. I have some old ones on plain paper, gelatino chloride and collodio chloride toned with acid platinum, and they have almost faded away. I am not well enough versed in chemistry to explain why this should be so; I give my own conviction founded on experience. Collodio chloride prints toned in a double bath, first alkaline gold followed by acid platinum, seem to be more permanent, and the makers of the various papers assure us that the pictures are permanent; but I have not used that process long enough to speak from my own experience. But I find with these latter a careful watch must be kept on the blotters in which they are dried.

A brother professional was greatly worried some years ago by having large numbers of silver prints returned to him which were covered with yellow marks and spots where the image was bleached, in some cases in large patches. For a long time he was at his wits end to discover the cause, and tried everything he could think of to prevent it; but it still went on. At last it was found. The prints when mounted were rubbed down, not with blotting paper as is usual, but with some ordinary white paper, bought for that purpose, and it was not noticed that the price of the paper had been getting lower and lower during the many years it had been used. The explanation was that at first the paper, when of a higher price, had been fairly pure; but, as time went on, inferior rags, perhaps coloured and dirty, were used in making the paper, chloride of lime was used to bleach the pulp, and hyposulphite of soda, or "antichlor," had to be used to neutralise the chloride of lime. So the carefully washed prints, while wet, were rubbed down with paper containing large quantities of hypo. The moral of this is, how extremely careful we must be in all our manipulations.—Yours faithfully,

HAROLD BAKER.

17, Cannon Street, Birmingham, November 6, 1905.

To the Editors.

Gentlemen,—I looked forward with the keenest interest for the letters on C.C. matt this week, but instead of learning anything I was grievously disappointed. One gentleman says he has had spots, but has not used the paper long, the other that hypo alone is the sole cause—a fact that I cannot reconcile myself to.

My candid opinion is, after working the process for four years off and on—that is, off when spots come, and then reattracted by the superb results the paper is capable of giving (better in my opinion than any other process except carbon) trying it again—that the process is unsuited to the climatic conditions of England, and that here at least it will never be an invariably permanent (I mean for silver) process.

In America, where C.C. matt (platinum-toned) is paramount, the climate is so dry that even platinum paper can be quite carelessly worked in winter; in summer no precautions at all are necessary beyond trying to keep it as cool as possible. Now, as C.C. matt is so sensitive to damp when finished, clearly, the moist atmosphere of England makes against permanency. I believe a C.C. print kept dry

is as permanent as any silver print can be—in fact, I have tested and proved it to be so, but can we guarantee that they will be kept dry after leaving our hands?

I have had prints brought back spotted all over after a few months, and have found that a copy in my possession made and finished at the same time was perfect. Even the prints in my doorway showcase will fade before the studio specimens lose their pristine freshness.

As I work single-handed, I know that no carelessness is to be reckoned with. I do not use blotting paper at all, but after swabbing moisture off face of print with a perfectly clean cloth for each batch, press into contact with waxed paper in mounting.

To sum up, I have found that under any condition a gold-toned only C.C. print is practically as permanent as any other silver print. It is only when gold and platinum together is used that instability is present. I have an opinion that the acid platinum bath rots the film and renders it more susceptible to atmospheric influence.

If one has to remove a small untuned spot which occasionally occurs in these prints one notices how much harder it is to scratch out that spot than the surrounding film, which seems quite friable in comparison.

No doubt careful working is a vital necessity, and I always use a bicarbonate of soda bath after the platinum and before fixing, but I am only waiting for a direct carbon process to be rendered practicable, when I shall abandon C.C. matt for ever. It must be remembered that the bulk of the work of the middle and lower class photographers is placed on the mantel-shelf of the parlour, that sanctum sanctorum of the British housewife, where the chancel house atmosphere is never dissipated by opening the windows or lighting a fire, for fear of dust gaining access, except perhaps for a day or so at Christmas, and an occasional Sunday. Here it is that our prints stand and become spotted and faded, in the damp chill atmosphere, and the poor photographer has to take the blame for roguery which he is not guilty of.—Yours faithfully,

November 4, 1905.

OTHELLO.

B. J. EDWARDS AND CO.

To the Editors.

Gentlemen,—This old-established business having been purchased from the late limited company, the manufacture of isochromatic plates and films and other specialities will in future be under the personal supervision of Mr. B. J. Edwards (the originator and founder of the business), whose name and long experience will be, as in former years, a guarantee of the excellence of all goods supplied.—Yours faithfully,

B. J. EDWARDS AND CO.

Castlebar Works, Ealing Dean, London, W.

November 6, 1905.

THE International Jury of the Liège Exhibition have conferred upon Burroughs, Wellcome and Co. six grand prizes, three diplomas of honour, and three gold medals, for the scientific excellence of their products. A prominent place in the firm's exhibit was given to "Tabloid" photographic chemicals, and an interesting display of prints illustrating processes carried out with the firm's photographic preparations.

We note in the "Express" that Bassano's, Limited, the Bond Street photographers, deny the statement that Mr. De Wend Fenton, who has been "warned off" the Turf, is in any way connected with their business, which is the property of the "Illustrated London News" and "Sketch," Limited.

"Nonna" developer and sepia toning was the subject of an interesting lecture by Mr. W. Sadler to the members of the Edinburgh Photographic Society on the 31st ult.

Answers to Correspondents.

- * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- W. Hone, 150, Shakespeare Street, Southport, Lancashire. Two Photographs of the Late Canon Blundell.
- D. M. Black, 93, Warton Terrace, Heaton, Newcastle-on-Tyne. Two Photographs of Desmond Dene.
- Mary A. Dugdale, 1, John Street, Bath. Three Photographs of the Church of St. John the Evangelist, South Parade, Bath.
- W. T. Dalton, 108, Chester Road, Northwich, Cheshire. Photograph of Holy Trinity Church, Northwich.
- W. E. Welchman, The Studio, Exchange Street, Retford, Notts. Photograph of one of the First Passenger Tickets issued by the Midland Counties Railway, now the Midland Railway, on July 28, 1838.

- J. Russell, 188, St. Albans Road, Watford, Herts. Photograph of Christ Church Choir, Watford.
- J. H. Cartwright, 171, Orford Lane, Warrington. Photograph (combination), Personal Post Card with "Seaside's Greetings from Warrington," and Eight Views.

REPRODUCTION FEES.—Would you kindly inform me in your "Answers to Correspondents" what is the usual fee to charge a publishing house for allowing them to reproduce postcards from copyright negatives? I am under the impression that it is usual to first charge 10s. 6d. for allowing them to produce 1,000, and afterwards so much per 1,000, but do not know the usual price per 1,000 after the first 1,000.—A. HUBBARD.

The Copyright Union recommend a royalty of 10s. 6d. per 1,000 for half-tone and colotype cards, and £1 1s. for bromide and P.O.P. cards. You will find these and other particulars of reproduction fees in the forthcoming ALMANAC.

E. S. (Peterhead).—We cannot say whether the process will be in professional use shortly. We see no signs that it will, though naturally people do not talk about their plans. We should say that of the processes now on the market it is the most promising commercially.

W. F. L.—If you will study the "Situations Vacant" and "Wanted" columns you will learn more than we can tell you in half a column, and you should then be able to draw your own conclusions.

X-RAY STEREOSCOPY.—In this week's B.J.P. you mention a reprint of a paper by William Cotton, M.D., on "Twin X-ray Representation and the Reflecting Stereoscope." Kindly say if I could obtain a copy, and how, and where.—H. B.

In the "Bristol Medico-Chirurgical Journal" for September, published by Churchill, 7, Great Marlborough Street, London, 1s. 6d.

COPYRIGHT QUERY.—I wish to ask you if I take cabinet negatives from registered pictures to print from for publishing, will I have to get those registered also?—W. HOVE.

If the copyright in the original pictures is registered it will cover the copyright in any reproductions made from it. They need not be registered afresh.

A COPYRIGHT QUESTION.—Would you kindly give an answer to this query:—"Is there any copyright in the idea of postcards, showing the eyes only; we have seen some of people taken this way, and would like to introduce this style to our sitters, providing it is not an infringement of rights?"—PROGRESS.

There can be no copyright in an "idea." There may possibly be a copyright in the pictures you have seen. But, of course, you produce others like them if you wish to do so, and make your pictures copyright should you desire to do it—that is, provided you are not paid for taking them.

BURLINGTON.—We should advise Plate No. 1 and a pyro-metol developer, of the formula given in the ALMANAC. Either Nos. 1 or 2 of the printing papers will be the best. The other is of too rough a surface.

RESIDUES.—1. What method have photographers of extracting gold from toning baths for sale to dealers? 2. Do photographers send waste P.O.P. to dealers in its natural state? 3. What price do dealers pay as a rule for residues?—F. COX.

1. Throw down the gold with solution of proto-sulphate of iron. 2. The refiners will quote for the paper. 3. Impossible to say; an assay must be made. You had better write to one or other of the refiners advertising in our pages.

COPYING BLUE ORIGINALS.—1. What is the best procedure to adopt, both as to plate and developer, to make clear glass and intense black negative from a blue print? Would a yellow screen assist? 2. What is the best method of obtaining equality of illumination of a large plan?—ANASTIGMITE.

1. Use a filter of equal parts of 1-10 per cent. solutions of acid-green and tartrazine, with an iso plate. You will find an article on this subject in the forthcoming ALMANAC. 2. Diffused daylight is the best, or, failing that, a pair of arcs. With gaslights you will find difficulty in illuminating a large plan evenly.

ANXIOUS.—1. The cause of the stain is undoubtedly insufficient washing prior to toning. This must be very thorough. In fact, we advise the immersion of the prints in a 10 per cent. solution of common salt for five minutes, then well washing with subsequent toning. 2. Certainly, but to some extent it depends upon the character of the paper. You can either dilute your bath with an equal quantity of water or, and this is preferable, use tartaric instead of citric acid. 3. To some extent the duration of toning depends upon temperature, but we find that fifteen minutes is a fair average. 4. Certainly, they are as permanent, if not more so.

G. H.—We gave a formula of the kind in our issue of May 19, but we will repeat it:—Potassium iodide, 80 grains; ammonium bromide, 35 grains; ammonium chloride, 10 grains; gelatine, 60 grains; albumen, 1 ounce; distilled water, 10 ounces. Soak the gelatine in the water and dissolve by the aid of heat; add the salts and allow to cool, and then add the albumen. Spread this solution over the paper or canvas with a soft sponge, and when dry sensitise with silver nitrate, 1 ounce, glacial acetic acid, $\frac{1}{2}$ ounce; distilled water, 10 ounces. A small pool of this should be poured on to the canvas or paper and distributed with a clean sponge or cotton wool, and the paper should be exposed wet. The developer is: Gallic acid, 60 grains; lead acetate, 10 grains; distilled

water, 10 ounces, and should be applied with the same sponge as the sensitiser is distributed, or a little silver solution should be added to above. For sepia tones it would be advisable to bleach with ferricyanide, and then apply sodium sulphide solution, about 1 per cent.

RETOUCHING (Reply to J. T.).—You will become an excellent retoucher when you learn to respect the modelling more than you now do. Your work is soft, solid in texture, and generally well blended, but the negatives have not given you fair scope. Bring the features out with additional lighting, and respect dimples and other distinctive marks. Get your effect with as little work as possible, and let it be in the right place. Smothering the faces with retouching usually eradicates strength and form, and only adds waxy prettiness, which in the case of male studies is simply (to our taste) detestable and unnatural.

PINHOLE APPARATUS.—About 1893-95, Mr. J. Favre Brandt, of Yokohama, made an apparatus for pinhole photography, which became known under his name. Can you tell me if this can be got anywhere?—C. FRED POLLOCK.

We believe from Adams and Co., 26, Charing Cross Road, London, W.C.

COPYRIGHT.—1. I have two prints of the pictures "Heads of Angels" by Sir Joshua Reynolds, in the National Gallery, and "The Light of the World," by Holman Hunt. I wish to copy these down to postcard size, and use the negs. for producing Christmas postcards. Can you inform me whether the sale of such cards would be an infringement of the law? 2. I see from the forms supplied by the Registrar of Copyright that the fee charged for a search is 1s., but am not clear as to whether this is simply the charge for use of the Registry only, or whether they will, for that sum, make a search to discover whether anything is copyrighted or not. 3. Can you tell me what their rules are in this respect, and also (if they do not undertake searches) to whom I could apply in London to make the search for me, and what fee would be charged?—SYLVIA.

1. If there is a copyright in the prints, as most probably there is, you would certainly be infringing the law by reproducing them in any form whatever. 2. The 1s. fee is for permission to search the register, and this you must do yourself, or get some one to do it for you. The Office does not undertake to make searches. 3. Perhaps you could get some friend in London; we know of no one who would undertake the work.

STUDIO QUERY.—I shall esteem it a favour if you will let me know whether I should have to get sanction from the council, or any other body, to place a portable studio in the back of my premises?—J. M.

We cannot say, but most likely you would. The local building laws vary in different districts, so also do the terms of tenancy upon which premises are let. We should advise you, first to see if there is any objection on the part of the landlord, and then consult the district surveyor before putting up the erection. He will tell you if the studio will contravene the local building laws.

OF THE ROYAL ARMS.—When out in India, I sent some photographs to her late Majesty Queen Victoria, and she wrote graciously accepting them. I want to ask if I could put the Royal coat of arms on my cards in consequence. If not, could I put: "Patronised by her late Majesty Queen Victoria"? I should be very much obliged to know which would be the correct thing to do.—MAGNET.

The fact that the late Queen Victoria accepted the photo-

graphs certainly does not entitle you to use the Royal Arms. To do that you must obtain the Royal Warrant, and that you will not do on the strength that her late Majesty merely accepted some of your pictures. You can hardly say that you were "patronised" by the late Queen, though she accepted your photographs.

P. M. KAY.—Guiterman and Co., 35-36, Aldermanbury, London E.C.

W. G. PAYNE.—You have only to "reduce" them with, say, Farmer's solution. Consult an elementary text-book.

J. WALSH.—The acid fixing is doubtless the cause. If you must have an acid bath, use a proper formula, such as hypo. 4 oz., potass metabisulphite $\frac{1}{2}$ oz., water 20 oz., or one or other of those given in the "Almanac." We will act on your suggestion.

A LECTURE QUERY.—Will you kindly inform me in the correspondence column on the following points for the purpose of illustrating a lecture on the "Art of Photography" in December next? 1. The publishers and prices of one or two reliable works on the history of photography, with details of early processes. 4. The names and addresses of some of our leading pictorial workers.—REGULAR SUBSCRIBER.

1. "Photography: Its History, etc.," by A. Brothers, 21s. "The Story of Photography," 1s., from Dawbarn and Ward, Ltd., 6, Farringdon Avenue, E.C. 4. See the catalogues of the Royal Photographic Society's Exhibition and the Photographic Salon.

LANCASHIRE and Cheshire Photographic Union.—The first council meeting of this union was held in the Manchester Amateurs' Rooms on Saturday, the 4th inst., when delegates representing twenty-eight societies in Lancashire and Cheshire met to elect officers, etc. The following are the officers and judges elected for the year commencing January 1 next, viz.:—President, Dr. C. Thurstan Holland, of Liverpool; vice-presidents, Rev. H. W. Dick, of Manchester; Mr. T. Lee Syms, Leigh; Dr. Brennan, Stockport; and Dr. Crump, Burnley. Hon. secretary lantern slide section, Mr. T. Hudson, Nelson. Hon. secretary print folio section, Dr. A. T. Lakin, Manchester. Hon. selection judges for slides and prints, Dr. C. T. Holland, Rev. H. W. Dick, Messrs. S. L. Coulthurst, C. F. Inston, J. J. Rothwell, and F. Whitaker, with power to add to their numbers; hon. judges for societies' competitions and exhibitions, Rev. H. W. Dick, Dr. C. T. Holland, Dr. Ellis, Dr. Crump, Dr. Lakin, and Messrs. S. L. Coulthurst, F. Anyon, T. Lee Syms, C. F. Inston, J. W. Wade, J. Shaw, A. E. Bellingham, T. Glazebrook, Tullock Cheyne and A. W. Cooper. The hon. secretary and treasurer is Mr. W. Tansley, 22, Chapel Place, Liverpool.

NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1906.

EDITED BY GEORGE E. BROWN, F.I.C.

THE whole literary and advertisement contents of the ALMANAC, it is satisfactory to state, are now passing rapidly through the printers' hands. The task of producing 25,000 copies of a volume of 1,616 pages is, however, no light one, and it will be December 1 before the printed ALMANAC can be delivered to the public. Individuals who have not yet ordered should do so at once through a dealer or bookseller, otherwise they will most probably be disappointed in obtaining a copy. The features of the ALMANAC are sufficiently well known, but attention may be specially directed to certain constituents of the forthcoming volume:—

1. *A Contents*, serving as a guide to the pages, and showing at a glance in which portion a given item of information is to be sought.
2. *An Index* of nearly every individual fact, formula, and paragraph, serving to take the consultant to his subject at once.
3. *Photographic Copyright*. A popular exposition of the subject in its present-day applications.
4. *Epitome of Progress*, classified and codified. A review of the year's work in technical and scientific photography; in which everything on a given subject is assembled at one place in the volume.
5. *Contributed Articles* by leading writers.
6. *Frontispiece*, in Barnet Platino-Matt bromide paper, of Miss Billie Burke.

The Tables, Formulæ, and other features of the volume have been revised and re-arranged, and, it is hoped, will meet with the approval of every one of the 25,000 prospective readers of the 1906 ALMANAC, which in mere size, the publishers must confess, is greater than any of its forty-four predecessors.

EX CATHEDRA.

The Daguerreotype Process.

The article on the "Restoration" of Daguerreotypes in our issue of the 3rd inst., has brought us two or three letters on the subject, two of which were published last week, and one the week before. In the latter a statement is made which may mislead some readers. The writer says that the treatment we described would not answer with a non-gilded picture. Again, Mr. C. Welborne Piper, giving his experience, in reply to that letter, writes: "My experiences have been confined to untuned images, and with these I have found that cleansing is a perfectly safe and easy operation if reasonable care is taken. I do not think I have ever met with a toned or 'gilded' image." If Mr. Piper will permit our saying it, we doubt very much if he has ever met with a Daguerreotype that was not "gilded," seeing that he has been successful in cleansing them with cyanide of potassium. We have seen thousands of these pictures, and have only met with one case in which gilding had not been done, and that was a plate in the possession of the Photographic Club which was thought to have been made by Daguerre himself; at any rate, it was one of the very earliest Daguerreotypes. Within about eighteen months of the publication of Daguerre's paper, Fizeau published the method of toning—"gilding" it was then termed—the image with gold, which not only enhanced its stability, but conferred a far greater brilliancy on the picture, and from that time it was universally adopted by everyone who worked the process. It may be taken for granted that, subsequent to the publication of Fizeau's method (1841) no Daguerreotypes were turned out that were not toned with gold, and comparatively very few were produced prior to that advance. We allude to these historical facts as showing the misconceptions existing in the minds of modern writers on some of the old and obsolete photographic processes. Mr. Piper says that methylated spirit must not be used for the preliminary operation. As a matter of fact, we have never used any other in the many scores of pictures we have "restored," but it has been free from the mineral spirit. We strongly suspect that the methylated alcohol used by Mr. Henderson's operator was really methylated finish, hence the resinous deposit which he failed to remove.

Pyro-soda—A Warning.

In the Court of Appeal, one day last week, a case was heard that should be of interest to photographers who employ the pyro-soda developer, and draw their supplies of the carbonate of soda (washing soda) from the oilshops. The case, briefly put, was this. Under the Merchandise Marks Act a retail oilman was convicted by the magistrates at Tunbridge Wells and fined ten shillings for selling soda

crystals (washing soda) which contained from 34 to 63 per cent. of sulphate of soda—Glauber's salts. The point for the appellant was that there had been no false description, inasmuch as what were sold were soda crystals, though the crystals were largely those of sulphate of soda. What is known in the trade as "soda crystals" is carbonate of soda—commonly called washing soda. In the end the appeal was dismissed, and the conviction affirmed, with costs. The case has a photographic interest. Many, in making up their pyro-soda developer, purchase the carbonate of soda at the nearest oilshop; or many amateurs, possibly, draw it from the domestic supply. This, as a rule, answers well; indeed, in the formulæ issued by many plate-makers washing soda is prescribed. It is cheaper than the crystallised carbonate of soda of the chemist, and answers, to all intents and purposes, just as well if it be tolerably pure. But in view of the fact that sulphate of soda is a restrainer of development, such adulterated carbonate as the one referred to above cannot be admitted, for while we are adding the accelerator we are at the same time also adding a retarder. A photographer who unknowingly gets hold of a bad sample of carbonate will probably blame his exposure, the temperature, or the long-suffering manufacturer before he locates the source of the trouble. Considering that pure crystallised carbonate of soda is not an expensive article, we should advise its invariable adoption. We always employ it ourselves, and would recommend our readers to do the same.

Colour-Photography Mysteries.

An irritating report is printed in the current issue of "Wilson's." The New York Camera Club had a visit, on October 12, from Mr. W. C. Smith, the inventor of the "Solgram" tricolour process. According to the report, Mr. Smith "treated his subject in a very masterly manner," and, after explaining the method of the "Solgram," "concluded by washing off a picture in its first stage which had been printed in a few minutes by the Cooper-Hewitt light." But in what the process consists we are left to guess, except in so far as the following illuminating passage explains matters:—"It is only necessary to print the picture in its initial stage for a few minutes, wash with water which gives a red and white picture, or, rather, a foundation for a picture. It is then dried, coated with a solution, again printed and washed, and a third coating applied which, after exposure, is subjected to a further washing, finally giving a photograph in colour." Judging as best we may from this description, we have heard of processes which must be very like the "Solgram" method, which, nevertheless, appears to make all the usual claims to novelty and simplicity so often repeated in prospectuses of colour processes.

Flashlight Liability.

A case of some importance to photographic dealers has recently come before an Australian Court. Our readers may recollect that some time ago we alluded to the damages obtained by a photographer from Messrs. Harrington and Co., of Sydney, on account of some "magnesium powder" which in his use had proved explosive. Messrs. Harrington have now taken action against Messrs. G. W. Small and Co., who supplied them with the powder, and obtained damages for £75, the sum claimed being £300. Messrs. Small's defence was that they had no such explosive material in stock, and had not at any time supplied an explosive powder for pure magnesium. The case is an instance of the liability of the vendor, and would probably obtain similar judgment were an incident of the kind to transpire in this country. No doubt Messrs. Small were themselves buyers of the magnesium, and by the long-winded methods of the

law they may be able to obtain compensation or damages from the next liable party.

Christmas Side Lines.

We think that a good deal more might be done in the average business to increase the turnover during a busy season by pushing somewhat the sale of frames suitable for the photographs sent out. In one business we know, every tissue has neatly printed in red the announcement that a variety of frames to suit the photograph it encloses may be obtained. A valuable advertisement is thus secured at a most trifling cost. Many small portraits look exceedingly well in one of the fumed-wood circle or oval frames, and if only one is sold with each dozen portraits the profit during a month of the busy season mounts up to a decent sum. The receptionist may feel her way in the selection of such frames, as very little experience will enable her to decide what will sell most readily. In general, we think a fairly good article will be found most suitable. Cheap frames of all kinds are now sold in such quantities by the large drapery and other stores that the photographer can hardly buy them any cheaper than the public. Something out of the ordinary run in quality of workmanship and delicacy of design, something which obviously, at a glance, enhances the appearance of the print, is what is required. More attention, too, might be given to tinting photographs. The amount of work required to slightly colour a dozen cabinets is comparatively small, but the increase in the price which can be obtained shows a good profit on the time expended. In many cases the difficulty arises that no colourist is kept, but we believe there are many fairly good colourists who could undertake such work at their own homes and return it promptly.

Shellac.

A recent paper before the Pharmaceutical Society touches on a number of points which may be noted by those who have occasion to employ shellac for varnish making or other photographic purposes. The author, Mr. John C. Umney, speaks of the large extent to which shellac is at present adulterated in commerce, and, indeed, can find no better description of the activity shown in this direction than "a fine art." One rough solubility test for the purity of shellac is petroleum ether, which should not dissolve more than 5 or 6 per cent. of it, and can be used as an approximate means of distinguishing between common resin and shellac. Bleached shellac, often directed for photographic varnishes, is not, however, so suitable as the pure, raw article, and details of the bleaching processes given by Mr. Umney will show why this should be the case.

Bleached Shellac.

There are two processes in common use for bleaching shellac. The cheaper method consists in dissolving the shellac in alkali, adding a solution of sodium hypochlorite, freshly prepared, and reprecipitating the shellac by addition of sulphuric acid. The bleached shellac is then well washed with hot water and "pulled" to free it from adhering water. Shellac bleached in this way does not form a clear solution in alcohol, as it still retains the natural wax. Moreover, it becomes insoluble in course of time, especially if not thoroughly washed. The second method is more costly, as it is more tedious, and certain trade secrets are connected with the manufacture. The wax is separated by filtering the alkaline solution, but the method of bleaching is substantially the same as in the first method, except that hydrochloric acid is used for precipitating purposes. Bleached shellac prepared by this method dissolves almost entirely in alcohol, and retains its solubility for a considerable length of time.

SPOTS ON C.C. PAPER.

THE correspondence which has arisen in our columns on this subject is interesting and also important from the point of view of the professional photographer, for if the prints turned out by him prove within the short period of a few weeks to be fugitive, he may lose considerably in reputation and business. There is, however, one fact, which we think has an important bearing on this question, and that is that this is the fourth year in succession that this defect on collodio-chloride paper has been ventilated in our columns at this particular period of the year.

We lay special stress on this point because it may possibly lead to a clue which will enable us to set the matter right.

There is another fact which, whilst not one of the factors in every case that is reported, apparently is established in the majority, and that is that these spots arise more particularly when the prints are first treated to a gold bath and then with a platinum bath.

If we consider *seriatim* the constituents of a sheet of collodio-chloride paper, we may perhaps arrive at a better understanding.

In the first place we have the raw paper, in regard to which there is no proof that it is any worse in quality for collodio-chloride than for gelatino-chloride emulsion. Next this raw paper is coated with an emulsion of barium sulphate, commonly known as baryta, in gelatine, with usually a hardening agent, such as alum.

Next we have the chloride emulsion itself, which, as a rule, contains, besides silver chloride, an organic salt of silver with some free organic acid, either citric or tartaric. Now, it is obvious that here we have no conditions differing from gelatino-chloride paper, save in the vehicle for the silver salts.

It has been suggested that there is also used a substratum to make the sensitive emulsion adhere to the paper. This may be so, we cannot say definitely, for, naturally, such a fact might be considered a trade secret. But we can at least say that, possibly save when an extremely horny collodion is used, and in the case of a glossy surface baryta paper—certainly judging from our own experiments with matt baryta paper—anything in the nature of a substratum is quite unnecessary.

Practically, then, we have in collodio-chloride paper absolutely the same conditions that prevail in gelatino-chloride, yet we do not hear of the particular spots being met with in the use of the latter.

There is one other fact which we should mention, and that is that it is stated, and we repeat the statement with all reservations, that baryta paper is now treated with citric acid in order to prevent the paper turning yellow. This may or may not be so. Certainly some samples of commercial baryta paper which we have tested show no acidity. Then, again, is there any proof that one class of this paper is sold for gelatine and another for collodion emulsions? There is no proof, and the probabilities are all against such a thing happening.

This being the case, then, why do we meet with these spots on collodion papers and not on gelatine? From what we have already said, it would seem obvious that the only possible explanation is in the vehicle. But, has it not been accepted for many years—more years than most of us can recall—that collodion is an absolutely inert substance as regards all silver salts, whilst, on the other hand, gelatine is not so?

Obviously, then, we must acquit the vehicle itself of any charge, and we may dismiss it without a stain upon its character. Briefly, we may dismiss the emulsion itself

—that is, the other ingredients—because they are practically the same as in a gelatine emulsion.

Thus, by a process of elimination, we are led to the methods of treatment. The particular defect of which we are writing usually occurs when the prints are first toned with gold and then with platinum. The former bath is usually alkaline or neutral, and the second always an acid one; not that this is of much importance, only that it necessitates washing in between. The important point is, however, that unless the print and the underlying film of gelatine are absolutely freed from soluble silver salts, a chloroplatinite of silver is formed, which is quite insoluble, and is also readily reduced by light. We have here, therefore, a possible cause of general yellowing. Is it probable that the spots are primarily due to the formation of this silver salt? Another point is that chloroplatinites coagulate gelatine, and are very tenaciously retained by the same, so that the gelatine of the baryta emulsion might retain traces of this salt, which would give rise to local trouble.

It may possibly be thought this is rather a far-fetched idea, the spots being so local, but do we not see an almost similar case of spots—possibly not exactly of the same character—occurring in albumen and other silver prints, which suffer from so-called sulphurisation.

The platinum bath being acid, it is obviously essential that we either make our fixing bath alkaline or wash out every trace of acid, otherwise we may get sulphurisation. Then, again, we may get a combination of platinum and hypo, which is extremely insoluble—that is, if the prints are not well washed after toning, and as the collodion is an absolutely inert vehicle, both as regards silver and platinum, it is obvious that the only thing that is likely to hold the platinum salt tenaciously is the gelatine of the baryta paper.

We do not lay special stress upon these points, but have rather advanced them that our readers may see that the subject is somewhat complicated, and if those who have met with these spots would let us know through our correspondence column their method of treatment, we might, by eliminating point after point, arrive at some satisfactory conclusion.

We have now to return to that particular fact on which we laid stress at the commencement of these notes, namely, "this is the fourth year in succession that this defect on collodio-chloride paper has been ventilated in our columns at this particular period of the year."

It is hardly necessary for us to do more than say that at the particular moment of writing, it is raining, and has been almost continuously for twenty-four hours. The ground is sodden with moisture, the air laden with it, and everyone who has recently tried to dry either negatives or prints quickly knows full well that now it takes more than double the time that it did three months ago. Hence it would appear that long continued damp plays no small part in the formation of these spots. If this is admitted, and we must confess the evidence, though somewhat circumstantial, is decidedly in its favour, then how much more likely are we to meet this trouble when prints are mounted. For at the back we have a thick card and a colloid vehicle as mountant, which naturally would retain moisture much longer than the print hung up to dry. As a matter of fact, we imprison moisture between the collodion film, on the one hand, and the thick and possibly glazed surface of the card on the other, and thus give the best possible chance for any latent mischief to develop.

This very last phrase that we have used may lead some to say that we presume that the mischief is latent, and therefore it must be present in unmounted prints, and

only requires congenial environment to manifest its presence. We believe this to be so, and that if a batch of prints treated absolutely alike were divided into two parts, the one mounted and the other left unmounted, and the former showed spots in a short time, then we believe that the unmounted prints, if mounted, would develop exactly the same symptoms.

Others may at once conclude from this that it is the mountant and card that may be at fault. It hardly seems probable that a number of men scattered throughout the country should be all simultaneously using the same make of cards and mountant. The disease seems too general to be ascribed to these methods.

The letters which have already appeared all point to the advisability of rapid drying, whether the prints be mounted or not, and, so far, this is the only advice we can give our readers. When the prints have been sufficiently washed, remove from the water, squeegee well with a roller squeegee, protecting them with thin celluloid or waxed parchment paper, mount, and dry quickly.

There are other points upon which it is hardly necessary for us to lay stress, namely, short, but effective washing. Long continued soaking in running water, or unnecessarily repeated changes of water—that is, up to four or five hours—are quite unnecessary, and the only result can be a partial disintegration of the baryta-bearing gelatine film.

We shall be glad to hear further from our readers on the subject, but would ask them to distinguish between yellow patches and small circular spots. To anyone with a little leisure and an inquiring mind, *plus* a microscope, we would suggest a little examination of prints affected by these fell diseases, and we would further suggest that after examining the surface of the print, the collodion image should be stripped or dissolved off and the baryta coating examined. We also shall be glad to receive samples, both of the yellow patch and "spotted fever" prints, with full details as to their production, in order that we may make a few investigations on our own account.

"PHOTOGRAMS" OF 1906.

Do you want a pocket Salon, a portable R.P.S., and a "tabloid" St. Louis all rolled into one? And *minus* the exhibition headache. Then buy "Photograms of the Year 1905." It will cost you a halfpenny a day for a month and a half; but can you afford to be left behind in the race of life for the sake of—

Tut-tut. I am forgetting myself, and unconsciously falling into the inimitable style of my favourite author. Please pardon the lapse. Truth to tell, I was imperceptibly influenced by an advertisement which caught my eye a moment ago, on page xxxv. of the very volume which I have set out to eulogise. It exclaims, in the largest, of underlined type: "CAN YOU WRITE ON LIVE PHOTOGRAPHIC TOPICS?" and proceeds to add that a certain Transatlantic contemporary "is always glad to receive articles on practical and timely photographic subject. Have you some pet 'wrinkle' for doing them?" . . . "Send it along, so that your co-workers may have the benefit of your ideas." I fancy that effusions on defunct photographic topics flow somewhat more easily from my pen than on "live" ones, whatever they may be; but in this instance I really pride myself that I have a "pet wrinkle" to offer. "Our co-workers" will find it embalmed in Sentence Three of Paragraph One, above.

But I am wandering from the point, as the negative said when it slithered off the retouching desk. Still, there is no doubt that the advertisement pages of a book like "Photograms of the Year" are often very nearly as edifying as the main contents. In the volume which lies before us, for instance, there are the usual number of pretty girls—with the usual variety of attire, from the Adamite fashions to that of the Photo-Secession cave-dwellers and the Tale of Unsold (beg pardon, Isolde) strips of string and paint. But the most absolutely stunning of the whole bevy is the damsel who is coaxing her digits into a kid glove on ad. page xxvi. and trying to see whether her hat is on straight by squinting at its reflection in the Videx finder on page xxvii. Undoubtedly, as the footnote exclaims, this "dims all others" in the "beauty and elegance of the form in which it is presented." I am quite unable to understand the haste to escape of the gentleman on page xxv., who is so flummoxed that he cannot even stop till the chairs have been taken out of his way. How *gauche* of him!

Enough of the fascinating ads., though I had fain devoted

a few lines to the touching scene on page xxi., and likewise yearn to pause and ponder on what "The World's Background Headquarters" (tantalisingly mentioned, without explanation, on page xxxix.) may be. Duty calls. We must turn at once to the main contents of the book.

The publishers will be the first to excuse me if I hint that, broadly speaking, the pictures are more vitally enthralling than the reading matter, excellent, and even exciting, though the latter is. It is doubtless harrowing to learn, for example, that the members of the Danish Royal Family are "passionate amateur photographers," and one wonders tremblingly whether the picture on the same page as this statement (74) represents one of these unfortunate monarchs in the frenzy of a seizure, and if so, whether the individual who had the temerity to snap him thus escaped in safety. The chronicler is silent, although speaking on the same page of "increasing the small number of amateur photographers" (by which we presume he refers to the murder of some of them by tempestuous sovereigns) he says, significantly, "the taste for this sport began to spread amongst the general public" which is bad hearing for any who are not (like the gentleman named lower down) "less eminent in the way of technical virtuosity." It is alarming, too, to be told that the Danish art critics refuse to take photography seriously. We suffer from a similar plague in England, and (when we come to think of it) for much the same reason which our author gives. (See page 78.) Danish amateurs, he moans plaintively, "snap away lively" (by the way, what a vivid picture "snap away lively" calls up! Surely our Transatlantic contemporary would have appreciated this) —"snap away lively at everything they see; at one time they take two pictures on one plate, and another time none at all." (Candidly, now, are the art critics so stony-souled as to refuse to regard even the latter course of procedure with approval?) "A church spire they take on the broad side, and a cow on the short side." (Never knew before that a cow had a short side. But perhaps Danish breeds of cattle are peculiar in this respect.) "I have even met amateur photographers, who have had a camera for years, and who have taken all the pictures on one side, because they have never thought, that only by turning the camera over, they could photograph on the other."

This is dreadful. We must organise an excursion of the Photographic Convention to Denmark, to show the benighted

inhabitants how to turn their camera over and photograph on the other side.

However, as I had already hinted when the article on "The Pictorial Effort in Denmark" (well named) enticed me off the track, the best part of "Photograms" two shillingsworth is not the reading matter, but the pictures, which include every kind, from the ones which are printed right way up to the ones which probably are. Ripping is the only word which I can apply to the blocks, which in several instances are a sight better than the originals—if so Philistine an expression of opinion be permitted. Some of the aforementioned pretty girls, sifted liberally through the book by a cunning editor, who is evidently determined to prevent the purchaser from getting even momentarily tired, are positively worth framing. If Mlle. Laguarde "aix" (page 106), at sight of such a model as her "Pierette"—well, I ache too; and as for the little lady on page 13—we have sent to Cook's to ask the fare to Coswig. Enough said.

Talking of portrait studies, what a wealth of expression may be observed in these throughout this book! Speaking likenesses many of them are—but it is just as well we can't hear what they're saying. The French for "Drat them fuddy-graffers" is, I am sure, unmusical, but I cannot help thinking it struck the tympanum of M. Charles Sollet when he immortalised the aged person who saves the cost of hair-restorer by using a duster, on page 8. And look at the cherubically chubby couple on page 16! Mama is murmuring, "Don't worry, dearie, if you've not got as many chins as I have. Your cheek feels promising, anyhow." Or take the sisters on page 19, who are grumbling, "If you'd only given us time to do our hair, we'd look much better-tempered." Or the "indifferent" kid on page 22. Indifferent? Of course he—or—she is indifferent. He—or she—is thinking, "Kisses are all very fine; but what I want is my clothes!" Or the bored urchin on page 45. Hear him groan, "How much longer have I got to play the fool like this?" Or the unhappy girl on page 78, who shrieks in despair, "If the world tilts any more, I shall fall off; but I'm more worried still about that boat on the horizon." With figure-studies such as these, the letterpress seems almost superfluous. Even Mr. Carter's "nervous English," which treats of such entrancing topics as "chemical grubs" in "scullery picture galleries" (page 108), is less eloquent than the illustrations that provide a text for his sermon.

Some of the pictures I do not approve of, and apparently the excited cypress tree on page 58 shares my opinion of the advisedly-vignetted "Perfume" which faces it, and squirms

accordingly. Is it fair, I ask also, to "register" (as the "Photogram" authors are so fond of expressing it) the agonies of a cow (page 86) which, like Bunyan's hero, has fallen into the slough, and is plaintively mooring to its old pal in the distance, "Won't you come and help to tug me out?" And why immortalise for posterity so flagrant a case of cruelty to easels as that on page 83, where Mr. Hopkins is almost audibly muttering, "Dash it all, hitting the thing seems to do no good. It's nearly as fuzzy as a photograph!" And wherefore thus publicly announce (page 111) that there is such a thing as a silly book by J. M. C. Grove? (Mem., to ask at the "Times" place in Bond Street for it. Perhaps it's an essay on the art of getting accepted at the Salon.)

Yes; there is no denying that some of the picture-titles are more enlightening than discreet. One on page 131 is a case in point. We are only too gratified to know from it that the fog is clearing away from the First American Salon; but recent remarks in an organ of the Press less well-informed than the editors of "Photograms" would have led us to suppose quite the reverse; and I question whether it was wise to refer to the matter at all. However, titles are often obscurer than they sound. For instance, does that on page 67 allude to the model, or her genial friend upon the table—or to the photographer? And who, I ask, is Marie Basse? (page 11). She sounds a most interesting young lady, and we have no doubt that she may have been at Boulogne some time or another, but the most careful scrutiny of M. Bucquet's picture fails to reveal her whereabouts. And why does Mrs. Cadby call her picture (page 100) "The Cat that Walked by Himself"? Positively he did nothing of the kind, for it is obvious that he was accompanied by a photographer. And talking of animals, we have heard of an ox in a teacup; but "Photograms" can go one better than that, inasmuch as Mr. Esendero (page 112) has got two of them on his plate.

I could continue captious criticism of "Photograms of the Year 1905" for pages and pages more, but the editorial blue pencil hovers aloft over my manuscript, so I must reluctantly desist. And after all, this book is, as I have said, simply a sort of composite exhibition (a jolly fine one, too!), and, as its foreword sapiently whispers, "It is better to do good photography than to abuse an exhibition's management, or impute evil motives to its supporters." I sit abashed—clear though my conscience is of any crime but incorrigible frivolity. Or rather, I don't sit; on the contrary, I jump up and hasten to the dark room to "do" some "good photography," in the hopes that it may have the honour of appearing in the pages of "Photograms of 1906."

SOLOMON SAGE.

THE WEEK IN HISTORY.

Herschel on November 17, 1842.

EXACTLY sixty-three years ago to-day Sir John Herschel communicated to the Royal Society what is described in the "Proceedings" as a postscript to a paper on the action of the rays of the solar spectrum on vegetable colours. Only a very brief abstract appears in the "Proceedings," but the paper adds some notes to the lengthy one on the iron and other processes which Sir John had read before the Royal Society several months previously. One of these was chrysotype, the process which is the lineal ancestor of platinotype. The ferrous image obtained by exposing a ferric salt to light was treated with gold chloride, and a picture in that metal thus obtained. Sir John Herschel's investigations into the printing possibilities of iron and other salts were marvellously widespread, and probably many of the facts brought to light by him are unknown to the modern worker.

Dry Gelatino-Bromide Emulsion.

Of the various guises under which the gelatine dry plate process was introduced to photographers, one celebrates its thirty-second anniversary on November 20. On that date, in 1873, Mr. R. Kennett patented what he termed his dried "pellicle." Mr. Burgess, in THE BRITISH JOURNAL OF PHOTOGRAPHY for August 15 of that year had written that: "The weak point of the gelatino-bromide emulsion is its liability to decompose. . . . In a moderate temperature it will keep for weeks, but in spite of all the antiseptics I am acquainted with, it will ferment if the thermometer rises above 70 deg. Fahr. I have therefore confined myself to the making of dry plates which will keep any time." Mr. Burgess here strikes at once the track which photographic industry has followed, and on July 18, 1873, appeared the first advertisement of gelatine dry plates ("The Week in History," July 14).

Mr. Kennett's improvement—it was an improvement at the time—was to avoid fermentation of the emulsion by drying it. This he did by heating the emulsion (after washing it) in flat dishes until it was reduced to a thick paste; when cold it was stripped from the dishes and placed in suitable frames in a drying closet. When required for use, it was only necessary to dissolve the pellicle in water and coat the glass plates with it.

"Process" in the Daguerreotype Days

Photo-engraving being the genesis of Daguerreotype, and evolved from it by the slow processes which Niepce and Daguerre, and afterwards the latter alone, worked out, it is curious to note that one of the first modifications of Daguerre's process took the form of a reversion to the original. In other words, the single-picture method of Daguerre in the hands of Claudet became the photo-mechanical process which the latter patented in 1843—on November 21. Claudet based his photo-engraving on the chemical composition of the Daguerreotype picture, viz., a more or less white image of (mercury) amalgam on a black surface of polished silver. Certain acid mixtures

he found would attack the silver, but not the amalgam. He employed "a mixed acid composed of water, nitric acid, nitrate of potash, and common salt in certain proportions, which, being poured upon a Daguerreotype picture, attacks the pure silver, forming a chloride of that metal, and does not affect the white parts, which are protected by the mercury, but this action does not continue long. Then, by treatment with ammonia, the chloride of silver is dissolved and washed off, and the metal being again in its naked state, or cleansed from the chloride, it can be attacked afresh by the same acid."

Claudet, in this same patent (No. 9,957, 1843), describes the production of a grain by submitting the plate to a boiling concentrated emulsion of caustic potash, by which "the state of its surface is so modified that the acid spares or leaves in the parts which it attacks a great number of points, which form the grain of the engraving." And, further, to increase the resistant properties of the plate, he applies the electro-deposition of gold on its surface. Gilded Daguerreotypes came into vogue, however, for reasons other than their amenity to the making of a permanent engraved plate.

HISTORICAL.

APPARATUS FOR FOREIGN MARKETS.

[The following notes form the substance of a letter sent to us for publication by a manufacturer, to whom they were addressed in the first instance by a customer in the Malay States. In publishing them we may be allowed to re-echo the wish of the writer that British makers of apparatus would hasten to realise the peculiar requirements of a hot, damp climate such as prevails in many countries most remote from sources of supply. The failure of manufacturers to appreciate the ordeals to which cameras, etc., are submitted goes towards stifling photography of the amateur kind, but, as the writer continues, the foreign merchants are displaying great interest in everything suitable for foreign climates, and are, to a great extent, ousting British goods from the market.—EDS., B.J.P.]

CAMERAS should be made of well-seasoned teak. No leather covering should be used, as it goes quite rotten in a few months. All points should be screwed together with brass screws. No glue should be used, as glued points fall to pieces in a very short time; in fact, I have seen the glue dripping out of the joints in a few days after arrival. No iron whatever should be used if it is possible to do without it. All plate-carriers for changing boxes should be made of brass, not iron. I saw some plate-carriers about a month ago (which had not been very long here) eaten away by rust to such an extent that they were quite useless. The bellows should be fixed to the camera by brass plates and brass screws, so that it can be easily taken off for renewal and cleaning. A leather bellows will become quite covered with mould in a single night, if there is rain about, and therefore it

is necessary to have it fixed in such a way that it can be taken quickly off for cleaning purposes.

Focal-plane shutters, etc., should be all built on the same lines as stated above, easily removed if necessary. I have been in this country about twenty years, and have seen many amateurs give up photography in disgust all on account of trouble caused by cameras not having been built to stand the climate.

I bought a focal-plane camera a few months ago. I bought it here, as I was in a hurry at the time. I have had to pay pretty heavy for my hurry, as I took only about a couple of dozen photographs with it before it became quite useless, all on account of glue, iron, leather, etc. It was a beautifully-finished camera, but it would not stand this climate, so after all my expense I am at present without a camera.

Makers or exporters who discharge orders, say, for scientific expedition parties, should beware of supplying for tropical use anything that will rust, or glue or leather, if it can be possibly done without; and in case aluminium fittings are thought of, it should be known that it stands tropical climates very little better than iron. I know this, as we have a lot of instruments sent out for the use of the Government Department, in which I work, fitted with this metal; the result is that there are parts of them which have never been used, as they are useless.

My dark-slides have a lot of metal about them, and I find whenever I want to use them I have to dust out a lot of powder, and repaint them with dead-black, before they can be used.

W. T. W.

PHOTOGRAPHIC CHRISTMAS CARDS.

[The recent letter from Mr. J. Leisk referring to a method of producing Christmas cards of a kind suitable to the season has brought us a number of requests for a description of the process in detail. We therefore reproduce Mr. Leisk's article from the ALMANAC of 1901.—EDS., B.J.P.]

THERE is nothing novel in the idea of a photographic Christmas card for specially-designed mounts with appropriate mottoes are sold, on which photographs may be pasted; but to the true lover of the art who prefers to have the whole thing photographic, and his own work, there is ample scope for the exercise of originality in both taste and design in the method I am about to describe.

The idea is to surround a photographic portrait or view with an

ornamental border bearing a suitable motto, both being printed on the same paper, so that the border frames the picture, which appears as if seen through it.

To proceed, make a draft board by arranging three or more rough boards together, and fasten by nailing other pieces across the back, and let the size be proportionate to the length and breadth of the plate you intend to use, 34 by 26 inches corresponds to the quarter-plate, and is sufficiently near to suit a half-plate also; on this board paste a sheet of cream or light-grey wrapping paper.

The proportions being the same, it follows that any design placed on a board constructed as above will, when photographed, have the same relative proportions in the resulting negative that it has on the board, you therefore begin by outlining in pencil a suitable space in the centre

of such form as your taste may dictate for the portrait, group, or view, leaving a sufficient margin outside on which to arrange the border. Next, having decided on the motto or Christmas wish, procure a number of small twigs of trees, currant bushes or the like, forked pieces, etc., all with the bark on. Cut these up and arrange them into rustic letters forming the desired words, and when complete proceed to attach them with glue to the border portion of the board, arranging the words in lines or curves according to taste, and put aside to dry.

The next step is to attach the border, the arrangement and design of which must be left to individual taste. It may be formed of sprays of creeping plants or any pretty leaves, with flowers, fruit, etc., attached by small tacks or black pins, care being taken not to cover the motto or to cross the outlined centre with the decorations, and as soon as finished it should be placed upright in a side light, the centre of the board being exactly on a level with the camera lens, and at such distance that the image of the board shall *almost* cover the ground glass focussing screen, sharply focussed, and two or three plates exposed to secure correct exposure.

Assuming that a satisfactory negative has been obtained, take a print from it on P.O.P. the size of the negative, and when printed sufficiently to show the pencil line round the central space remove it, and, with a sharp knife cut out the centre along this line, and expose both the mask and disc thus obtained to plain daylight to blacken as much as possible. Then paste the disc (blackened side up) over the back of the negative, and carefully adjust it in register over the part to which it corresponds.

Next, having selected the negative which is to form the subject of the card, attach the mask in like manner to the back of it (dark side up), and so adjust it that the desired portion of the subject shows through the central opening. Both negatives are now placed in the printing frames, and a print taken from each, when one print will have a blank centre and the other a blank border, but these are now transposed, each to the other negative, care being taken by looking through them to see that the register is correct before closing the printing frame when a second exposure is made, which completes the printing of two copies, and so on. Having the two negatives, it takes no longer time to make two prints than it would printing from a single negative.

The object of placing the mask and disc on the backs of the negatives is to cause a slight vignetting through the thickness of the glass which causes the print and border to blend together, and prevents any slight error in the register being observed.

If our border design be arranged the vertical way of the board for portraits, and another the horizontal way for views, and a negative made from each, it follows that quite a number of subjects may be printed with the same borders, and when tired of one design fresh ones can be made with little trouble and at a nominal cost.

J. LEISK.

New Society for Margate.—A photographic and scientific society has been formed at Margate. At a meeting on Thursday, Dr. Warwick Brown was elected president, Dr. T. S. Rowe and Dr. Blagdon Richards vice-presidents, and the committee was formed as follows:—Dr. A. Rowe, Mr. F. Stanley, Mr. F. Dannon, Mr. F. Reeves, Mr. G. M. Macfarlane, Mr. S. Shea, Mr. A. Hobday, Mr. L. Adutt and Mr. G. E. Houghton. Mr. H. R. Gibbs was elected as hon. secretary, and Mr. F. M. Dunstan as hon. treasurer. Rules were adopted, and it was decided to hold meetings on the first and third Wednesdays in the month at Mr. Houghton's studio.

VACANT DATES.—Mr. Woodhouse Parkinson, hon. sec. of the Whitby Camera Club, writes us that he would be glad to hear of any lectures or demonstrations to fill a few vacant dates. His address is Ocean Road, West Cliff, Whitby.

EXAMINATIONS IN PHOTOGRAPHY.

From the report of the Examinations Board of the City and Guilds of London Institute we see that at the examination held in May last 118 candidates presented themselves out of 648 registered as students in classes. Of these the proportions of successes and failures were as follows:—Ordinary Grade—first class 16, second class 37, fail 50; Honours Grade—first class 5, second class 6, fail 4: a total percentage of failure of 45.7.

The questions set in the written paper of the "pure photography" section of the Ordinary Grade were as follows:—

1. If you were buying a high-class new lens for general purposes, what qualities would you require to have, and how would you test it to ascertain whether it really possessed them? (30 marks.)
2. It might happen that although the image was sharply defined on the focussing screen, the developed image on the photographic plate was not sharp. What are the possible causes of this difference, and how would you find out to which cause the defect was due in any particular case? (25.)
3. What are the more common defects in wet collodion negatives, and what are their causes and remedies? (25.)
4. Describe fully how you would develop, fix, wash, and dry a length of roll film exposed in a hand camera in a very bright light. Give the formulæ for your developer and fixing bath respectively. (30.)
5. Describe, with sketches if possible, the arrangement of glass and blinds that you prefer in the portrait studio. Describe your favourite method of lighting the sitter for a "head and bust" portrait. (25.)
6. If you have to photograph a group of people out of doors, what kind of background and lighting do you prefer, and how would you arrange the people composing the group? Give reasons. (25.)
7. You are required to produce on bromide paper a photographic copy of a line drawing. Describe fully the various steps in the production of the negative and print, and give formulæ for the various solutions used. Give reasons for any special procedure or precautions. (30.)
8. Describe how you would wash thoroughly (a) negatives and (b) prints, if running water were not obtainable. Give reasons for your methods. (25.)
9. What do you know about the properties of formalin and its uses in photography? (20.)
10. What are the uses of metabisulphites in photography, and what are their advantages and disadvantages as compared with ordinary sulphites? Give a formula for a developer made up with potassium metabisulphite. (25.)
11. Describe the stains most commonly met with on gelatino-bromide negatives, gelatino-bromide prints, and gelatino-chloride prints. State in what cases they can be removed, and how. Explain the causes of each stain as far as you can. (30.)

In the photo-mechanical processes section the questions were:—

1. Describe the camera, lenses, and appliances necessary for the production of negatives for half-tone blocks. (35.)
2. What is the object of employing diaphragms, or stops, in the making of negatives? Describe the use of irregular-shaped stops for half-tone negatives. (35.)
3. What are the constituents of a silver bath for the wet collodion process? (30.)
4. What intensifiers are in general use for the making of negatives for process blocks (a) by the wet collodion, (b) collodion emulsion, and (c) dry-plate process? (40.)
5. Describe the processes of printing on metal, for line blocks or zinc, and half-tone blocks on copper. (35.)
6. Give a short description of preparing negatives for the three-colour process by both the direct and indirect methods. (40.)

7. How are blocks made from three-colour negatives? State shortly the methods of printing on metal, etching and proofing. (40.)

8. Describe generally the process of etching line blocks on zinc. (40.)

9. Describe generally the process of etching half-tone blocks on copper or zinc. (40.)

10. State what you know about the printing of three-colour blocks; the kind of inks and paper, the order of printing, and how the separate printings are registered. (40.)

In the Honours Grade (pure photography) the questions were as follows:—

1. What do you know about the action of light on mixtures of potassium bichromate with organic substances? In what photographic processes is this action utilised, and in what way? (30.)

2. Describe fully the preparation of collodio-bromide emulsion for lantern slides. Describe also the method of developing the exposed plates, and give formulæ for the developers you use. (25.)

3. Describe all the adjustments required when enlarging by artificial light in order to secure (a) good definition, and (b) uniform illumination. Give reasons, and illustrate your answer by diagrams. Mention any special difficulties that may arise with particular sources of light, such as incandescent gas, and explain how you would surmount them. (30.)

4. Describe printing processes for copying engineers' drawings (a) as white lines on a black ground, (b) black lines on a white ground, and (c) white lines on a blue ground. Explain the chemical reactions on which the several processes are based. (30.)

5. Describe as fully as you can the relative advantages and disadvantages of pyrogallol on the one hand, and the newer developers on the other, for the development of negatives on gelatino-bromide plates for (a) portraits, and (b) landscapes. (25.)

6. Explain fully how you would develop plates which were somewhat stale, and the exposures of which were uncertain. Give reasons. (25.)

7. What do you know about the appearance and properties of the following substances, and their respective uses in photography:—Formalin, potassium metabisulphite, cadmium bromide, zinc bromide, acetone, glucose, dextrin, hydrogen peroxide? (25.)

8. How would you prepare a rapid gelatino-bromide emulsion? Explain the reasons for the various steps in the process, and state what chemical changes take place. (25.)

9. Describe in detail the production of a photographic transparency in natural colours by the three-colour process. Explain the principles on which the method depends. (30.)

10. What do you know about the theory and practice of printing on platinum? What are the advantages and disadvantages of the process? (20.)

11. Describe the construction, action, and use of a telephoto lens. Illustrate your answer by diagrams. (25.)

12. Discuss as fully as you can the resemblances and differences between the effects on the photographic image of the use of (a) a rising and swing camera front, with a fixed back, and (b) a rising but rigid camera front and a swing back. (25.)

In the photo-mechanical sections (Honours Grade) the students were asked:—

1. Describe the apparatus and appliances required for the production of negatives for line, half-tone, and three-colour blocks. (40.)

2. In the making of negatives for half-tone blocks, what essential qualities are necessary in order to produce the maximum of picture effect as apart from simply breaking up the subject into dots? Give details of working. (40.)

3. Describe fully the working of (a) the wet collodion process, (b) the collodion emulsion process, and (c) the dry-plate process, for the making of negatives for line and half-tone blocks. (40.)

4. What is the effect or advantage (if any) of employing elongated or irregular-shaped diaphragms in the preparation of negatives for three-colour blocks? (30.)

5. Have the colours used in "light filters" for three-colour negative any effect on the focal length of separate images, and if so, what steps may be taken to make the pictures coincide? (40.)

6. Describe fully, giving formulæ, the methods of preparing negatives for three-colour blocks by the direct and indirect processes. (40.)

7. Give formulæ and details of working for the printing on metal of negatives for line and half-tone blocks. (35.)

8. Describe fully the process of etching line blocks on zinc and copper. (40.)

9. Describe fully the process of etching half-tone blocks on copper and zinc. (40.)

10. Describe fully the process of etching of three-colour blocks on copper or zinc. (40.)

11. Give formulæ for the preparation of both liquid and dry light filters for three-colour negatives, and state which colour sensations are affected by each separate filter. (50.)

The practical examination in the Honours Grade, section A. (pure photography), consisted of two of the following exercises:—

1. Develop, fix, and wash the two exposed plates supplied. From the best of them, whilst still wet, make a print on bromide paper.

2. Photograph the drawing supplied, using a camera on an ordinary tripod. Make the longest side of the drawing 5 ins. Develop the plate so as to obtain strong contrasts.

3. Prepare lantern slides by contact and prints on "gas-light" paper from each of the two negatives supplied.

In the photo-mechanical processes section the exercises were selected from the following:—

1. Line Block.—Make a negative from a line drawing by the wet collodion process. (40.)

Print a line negative on zinc by the albumen process. (40.)

Etch a line block on zinc from a prepared plate. (50.)

2. Half-tone Block.—Make a half-tone negative from a photograph or wash drawing. (40.)

Print a half-tone negative on copper by the enameline process, and "burn in" the plate. (40.)

Etch a half-tone block from a prepared plate. (40.)

3. Three-colour Blocks.—Make a set of half-tone three-colour negatives, by the direct method, from a coloured original. (50.)

Make a set of continuous tone or plain three-colour negatives, by the indirect process, from a coloured original. (50.)

GRANTHAM Industrial and Fine Art Exhibition. —The nineteenth annual exhibition has been fixed for January 17, 18, and 19, with His Grace the Duke of Portland as President for the year. There are 111 classes for competition, including painting in oil and water colours, photography, carving, etc. Particulars and schedules can be obtained from Mr. George Jackson, Launder Terrace, Grantham.

A NEW Camera Club.—A meeting of the newly formed club in connection with the central Presbyterian Association was held last week in the Assembly Buildings, Belfast. Mr. J. A. Culbert was elected hon. treasurer, and Mr. James Gamble hon. secretary to the club.

SOME specimens of enlargements in black and white have been submitted to us by the Portrait Artists' Association, 33, Theobald's Road, Holborn, W.C., whose work we can describe as excellent, even at the extremely low prices charged for them. The firm, of course, must be the best judge of its own policy, but we could wish to see a revolt against the extraordinarily low prices which are frequently charged for hand-finished enlargements.

Exhibition.

CROYDON CAMERA CLUB.

THE eighth annual exhibition of this Club was held at the Horniman Hall, Croydon, from the 8th to 15th inst. Taking the exhibition as a whole, the show may fairly be considered as a strong one, the members' work showing a distinct and gratifying all-round advance. There were no less than eleven classes, which might have been reduced with advantage. In the championship class—very weak in point of numbers Mr. A. Marshall gains the silver-gilt plaque for "A Dusty Day." In Class B (Landscape, etc.) a somewhat poor one, Mr. F. Judge bears off the highest award for a small print entitled "September," somewhat sombre in tone, but of nice composition and feeling, whilst Mr. A. T. Bunce takes the second for an atmospheric rendering of the Thames Embankment. A gum print by Mr. J. S. Atherton in this section deserves notice, not only for its remarkably close resemblance—intentional or otherwise—to a water-colour drawing in monochrome. Class C (Portraiture and Figure Studies) is much stronger than the preceding. Mr. A. Marshall again scores a silver plaque, with a representation of two fisher maids, apparently quite unconscious of the presence of a camera. The repetition of the quaintly outlined sails, of a series of stationary fishing smacks, gives a certain originality to a well composed and happily thought-out picture. Mr. Oscar Hardee secures the bronze with a clever portrait of a lady. Class D (Architecture) is somewhat weak numerically, and fairly level in merit throughout. Mr. J. Dunlop and Mr. S. G. Kimber each obtain a bronze plaque. The Rev. H. Dick and Mr. E. Seymour in Class E (Lantern Slides) bear off the honours in the order named; whilst Miss J. E. Allan obtains a bronze plaque in Class F (for ladies only). The foregoing were all open classes, the last five available only to pictures which had not gained a previous award in any open class. The following applies to members' work only. Class G (Landscape, etc.), the silver medal goes to Mr. H. P. C. Harpur, for "The Bridge," to some extent a self-made subject, but cleverly treated by a clever worker. This picture, however, does not improve with further acquaintance. Mr. C. H. Austin receives the bronze for a breezy representation of a sailing fishing boat, full of life and go, and of excellent quality. This class is certainly stronger than its equivalent in the open class, and comprises many pictures which considerations of space alone prevent us from noticing. Messrs. Harpur and Austin again receive the two awards in Class H (Portraiture), the latter taking first place with a well-rendered child study, and the former the second place with a happy portrayal of two Dutch Meisjes. Some of the portraits in this class are very poor indeed, and it is a pity the Hanging Committee did not see their way to excluding them. Mr. G. L'Epine Smith, in Class I (Architecture, etc.), takes the bronze plaque (the silver having been withheld) with a gum print, "A Study in Straight Lines." In Class J (Any Subject) Mr. F. J. Terry is awarded the silver plaque for a rich carbon print of Bosham, having quite a painter-like quality. The bronze is gained by Mr. C. B. Tahourdin for a good technical print, but of unfortunate colour. In Class K (Lantern Slides) Mr. Harpur again scores, followed at no great distance by Mr. Walter Wood. The judges were Messrs. Henry W. Bennett and James A. Sinclair.

In addition to the exhibits, lantern and other entertainments and lectures were given in the evenings, together with carbon and platinotype demonstrations at intervals. The platinotype portrait lamp was also in full swing, and we were much struck by a modification in its working, planned for the occasion by its inventor,

Mr. W. H. Smith, and which we hope to refer to in more detail at a later date.

The exhibition, although excellent in every way, did not appear to have been sufficiently advertised. Beyond one small solitary poster crowded with printed matter, at a by no means prominent entrance, no further indication of the existence of the show was in evidence. This lack of publicity is likely to have made itself felt in the attendance.

Patent News.

Process patents—applications and specifications—are treated in Photo-Mechanical Notes."

The following applications for patents were made between October 30 and November 4.

ROLL FILMS.—No. 22,104. Improvements in means for rolling photographic films. La Société Anonyme Périphote et Photorama, 23, Southampton Buildings, London. [Date applied for under Patents Act, 1901, November 5, 1904, being date of application in France.]

PRINTING FRAME.—No. 22,219. An improved photographic printing frame. Frank Ingham, 88, High Holborn, London.

VIEW FINDERS.—No. 22,259. Improvements in finders for camera. Gustav Geiger, 6, Lord Street, Liverpool.

FLASHLIGHT.—No. 22,294. Improvements in or connected with flashlight photography. Harry Kirby, Tower Chambers, Halifax.

DAYLIGHT-LOADING CAMERA.—No. 22,339. A daylight-loading camera for plates and flat films. Frederick Thomas Stokes, 55, Chancery Lane, London.

PRINTING FRAMES.—No. 22,366. Improvements in photographic printing frames, W. L. Parkinson, 62, Dale Street, Liverpool.

ENLARGING APPARATUS.—No. 22,469. Improvements in negative-holders for photographic enlarging apparatus. W. T. Turner, J. W. Turner, and Robert Hope, 4, Clayton Square, Liverpool.

COLOUR EFFECTS.—No. 22,580. A process of reproducing photographs in natural colours. Edward John Browne, 7, Bendemere Road, Putney, London.

PRINTING FRAMES.—No. 22,582. Improvements in photographic printing frames. William Ecker, junr., 18, Fulham Place, Paddington, London.

CAMERA ATTACHMENTS.—No. 23,590. Improvements in and relating to attachments for photographic cameras. Nicholas Wladimiroff, 111, Hatton Garden, London. [Date applied for under Patent Act, 1901, November 5, 1904, being date of application in France.]

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

PLATE and Film Developing Apparatus.—No. 6,657, 1905. The patent is for a portable developing box having entrances and exits for developer, etc., and having red glass screens through which the plate or film may be inspected during development. The novelty of the claim is in the application to such a box of a red glass slide set at a suitable distance above the red glass bottom and grooves for receiving a dark slide while the plate or film is being transferred from it to the box; of a covering slide for the red glass slide, the covering slide being furnished with an inspection aperture glazed with yellow glass and provided with an opaque covering flap. Louis Gritte, Lacontiere Seine-et-Marne, France.

APPARATUS for Developing, etc., without a Dark-room.—No. 24,910.

1904. The claim is for a developing device in which variously coloured slides can be introduced between the eye-piece and a developing chamber to prevent the access of injurious light to the developing chamber so as to render it possible to make the sides of the bath of colourless glass, celluloid, or the like; also for a bath for use in the developing chamber described in the specification of Letters Patent No. 19,164, of 1904. This bath consists of two side parts, each provided with a glass or celluloid plate, and of a gasket, or packing of rubber or the like which can be compressed between these two side parts so as to ensure that the bath is liquid tight; and for use in connection with the developing chamber described in the specification of Letters Patent No. 19,164, of 1904. The dark slide is of materials not affected by the chemicals used and consists of a frame closed on each side by a sliding plate hermetically closing it so as to prevent the light from getting access to the sensitised plate contained therein. The dark slide can be hung directly in the bath and the development is effected after raising the two side plates without removing the sensitised plate from the dark slide. Hans Tirmann and Hugo Tirmann, of Pielach, near Melk. Province of Lower Austria.

CAMERA Improvements.—No. 4,515, 1905. The patent is for providing a camera in which the body can be racked right up to the front for the purpose of obtaining a "short focus." As at present constructed, when the body of the camera is racked or pushed up to the front or the front racked or pushed back to the body for a "short focus," the bottom of the body or the racking pinion comes into contact with the front stretchers, which stops them at a distance of from about 1 in. to $1\frac{1}{2}$ in. apart, a distance which does not permit of such a "short focus" being obtained as is sometimes required. Also in cameras constructed with the front stretchers inclined forward from the front, though a "short focus" can be obtained the long focus is correspondingly reduced. This invention is designed to overcome both these objections, and consists essentially in mounting the front and front stretchers on a bracket of elbow shape or a bracket formed with a slot or recess under or into which the racking pinion or clamping rod, and the bottom of the camera body can slide so that the body may be racked or moved close up against the front, or where no racking pinion or clamping rod coming against the stretchers is used the bottom of the camera body may be slotted so that the front stretchers or the plate on which they are mounted may slide or fit into same as the camera is moved forward. The Thornton-Pickard Manufacturing Company, Limited, Altrincham, and G. A. Pickard, of the same address.

PRINTING Frames.—No. 3,192, 1905. The patent is for a printing frame enabling the whole of the print to be examined, whilst being printed without shifting it. One end of the frame is provided with two blocks, serving, in conjunction with the inner faces of the sides, as stops for the negative and for the sheet of sensitised paper. The opposite end of the frame is combined with the clamping bar of a length corresponding to the space between the two sides. This bar is movable upon a screw which passes right through it and is held in place by a wing nut which tightens the bar against the end of the frame. The clamping-bar is rabbeted throughout its length so as to leave a space between it and the end of the frame sufficient to receive one of the edges of the negative plate and sheet of paper. Two pins serve to guide the clamping-bar in its movement and to hold it in the desired position. The plate and the sensitised paper are thus secured by one of their edges by

means of the rabbeted part of the clamping-bar, they are thus covered, as in ordinary frames, with a board held in place by a locking arrangement consisting of a pivoted bar combined with a spring upon which it presses. To use the frame the spring pressure-bar is first turned on its pivot and the covering board removed. The nut is then slightly loosened so as to allow the clamping-bar to be raised to a small extent, one of the edges of the negative is placed between the end of the frame and the edge of the clamping-bar, and the sheet of paper to be printed is similarly placed in position. The nut is screwed up again in order to clip the plate and the sheet of paper, which are thus fixed, and the board is replaced on the top and fixed by means of the pressure-bar. To examine the proof during the printing the back-board is removed, and the paper can be lifted without any disarrangement taking place of either the print or the plate. Louis Gritte, Lacontière, Seine-et-Marne, France.

FOLDING Photographic Camera.—No. 4,831, 1905. The patent is for a folding pocket camera. It consists of an articulated structure forming the frame which is adapted to receive a dark slide or be combined with a magazine plate or film carrier. This frame is capable of folding closely and without loss of space between the two rigid sections and in the manner of a purse, and when folded is kept shut by the aid of a combined finder which acts as a clasp. When the camera or frame is

opened its shape is maintained by a hinged sheath or slide guide which receives the dark slide or plate magazine or film carrier. This sheath is formed with a three-sided extension or surround, the hinged sheath acting in conjunction with guide plates arranged at each side, which secure absolute rigidity when the camera is opened. In order to ensure rigidity and to guide the folding and opening movements of the front parts of the metallic sides *a b* with respect to the rest of the articulated frame, slotted guide plates *m n* are fixed in pairs to each of the inner faces of the side plates *a b* and out of the way of the rays from the lens. One of these guide plates in each pair of the right and left set is formed with a slot at *o*, in which slides a pin *g*, carried by the other guide plate in each pair. Thus the slotted guide plates and the pin plates guide each other and the guiding and stiffening means are wholly independent of the sides or rigid side supports. The slotted guide plate arrangement ensures the perfect guiding of the parts in opening and closing, preserving the whole structure perfectly rigid, both vertically and laterally, and preventing one-half deviating from the other in their respective movements. The lower part of the rear frame or sheath *c* is prolonged on its exterior on three sides or is formed with a sort of surround *c'* which, when the camera is folded, envelopes the upper half of the rear frame or structure *c*, which forms part of the sheath or guiding means for

the slide or plate carrier. This upper half it protects both laterally and across the entrance slot, and prevents the admission of dust into the camera when closed and carried in the pocket or otherwise. This extension or three-sided surround *c* also protects the light proof stuff where it covers when folded. When the camera is shut or folded it is maintained clasped by the instrumentality of a suitably designed finder such as *v*, which is hinged at *v'* upon the edge of the upper side *a*, or upon a plate secured thereto, so that said finder *v* can be turned down and clasped to the lower side *b* by a button or fastening *u*, which engages a slotted catch plate *t*, mounted on the lower side *b*. The fastening means carried by the pivoted finder and lower side of the camera may be varied. The pivoted finder bridges the end space between the stiff sections *a* *b*, and makes an efficient clasp. Emile Pipon, 218, Boulevard Raspail, Paris.

New Materials.

A New Grade Griffin's Bromide Paper. Made by J. J. Griffin and Sons, Limited, 20-26, Sardinia Street, London, W.C.

The good qualities of Messrs. Griffin's bromide papers are already too well known to need further commendation from us. A new variety has now been placed on the market, and prints made on it exhibit the same points of excellence made familiar by the firm's other grades. The new paper is named "Natural Surface," and its characteristics are the richness of the blacks obtainable and the purity of the whites. An amidol developer is recommended, and with this there appears no difficulty in obtaining in the print all that the negative has to give. The surface of the new paper can hardly be described as matt, as there is the slightest possible indication of gloss. This tends to give great depth to the shadows, and, at the same time, assists the detail in high lights and half tones. The prints have a peculiarly lustrous appearance, which is very effective, and should prove acceptable to every photographer who, while disliking a glazed surface paper, does not want one so rough that the finer details of his work are lost. The paper is sold in 6d. packets up to 6 by 4½ in., and in 1s. packets up to 10 by 8. Larger sizes are sold in handy packets of four pieces each up to 25 by 21 at popular prices.

Christmas Card Mounts. Sold by Houghtons, Limited.

Messrs. Houghtons' list of cards we have reviewed already, and we have said of it that, in so far as half-tone illustration is able, it puts the selection before the reader. The missing element of colour in the reproductions is supplied, but only inadequately, by the written description under each design. Nothing but half-tones in colour will completely meet the case, but we may, perhaps, step into the breach with Messrs. Houghtons and endeavour to convey to the distant purchaser the effect of some cards which have particularly pleased us. For example, No. 1727, cold brown with a pale green lettering ("Greetings") is quite dignified and refined. No. 1735 is in lavender grey with white insertion, as they say in St. Paul's Churchyard, and the words "With Best Wishes" in neat gilt lettering completes a dainty mount, feminine in character. But No. 1732 is bold and strong, vivid red with a little black and a good deal of white—a card to offer with the preceding, if one would range from opposite to opposite of tastes. No. 1720 is neat: like all those before us, it is a neat folder of the slip-in kind; nut-brown with gold lettering, and tied with a ribbon of darker brown. No. 1759 is another grey and gold, produced in good taste. We may say that the prices of the mounts run about 1s. 9d. to 4s. per dozen.

and for one thing above all others are Messrs. Houghtons to be thanked. They have cut the "greeting" down to a crisp phrase on each card. No stanzas from Tennyson, or perfervid lines from the poet-to-order at half-a-crown a time.

New Books.

"Beasties Courageous." By Douglas English, B.A. London: S. H. Bousfield and Co., Ltd. 5s.

It is difficult to decide, after perusing this latest production, from the camera and pen of Douglas English, whether his photographs of "beasties courageous" or the delightful little stories he has woven around them calls for the greater amount of praise.

That Mr. English is a master in his own department of nature photography needs no telling, and the present example of his patient industry and skill with the camera but enhances a previous high reputation.

Never before, perhaps, have the habits and lives and characters of our unconsidered little friends, the mice, voles, toads, and other field-folk, been so cunningly and delightfully put before us, and it is with more than ordinary interest we follow "the daring of the woodmouse," "the unjust tribulations of the toads," or "the vengeance of Jump-Jim-Crow." Every reader of "Beasties Courageous" will, we are sure, give in the future more than a passing thought to the little people whose world is here so cleverly portrayed, and if only this end is achieved our author has done something to be proud of.

A note of tragedy and mystery, too, is struck in the chapter, "The Keeper's Tree," that betokens a power of literary ability giving promise for the future in fields other than those inhabited by natural history specimens, and it is with genuine regret one lays down the volume after reading the concluding adventures of "Coubulo and Penelope." We congratulate the author on this book, and look with pleasurable interest for his next. As a gift-book, we can conceive nothing more acceptable. It contains fifty-six pages of illustrations on plate paper, and a photogravure frontispiece.

"THE PHOTO-MINIATURE."—No. 73 of Mr. John A. Tennant's monographs on photography concerns panoramic work, and is briefly historical and commendably practical. It contains some useful hints on the photography of tall buildings in narrow streets by making several negatives. The "P.-M." is supplied by Messrs. Dawbarn and Ward for 6d.

"THE Magazine of Fine Arts" is the title of a sumptuously gotten-up periodical that makes its first appearance this month from the house of George Newnes, Limited, Southampton Street, Strand, W.C. This new magazine will be concerned chiefly with the best in the art of many centuries, and the treasure stores of every country in the world will be drawn upon. Arts and crafts that are old in years, but as fresh as a new discovery to the majority of art lovers, will be dealt with in its pages by British and foreign experts capable of imparting valuable information in a readable manner. An ambitious programme truly, but, on the standard of the first number, capable of achievement. The illustrations, both in colours and monochrome, are numerous and good, and they should render the magazine valuable to collectors of artistic objects, as well as to art students, who will appreciate an illustrated review of the fine and decorative arts of other days. Published at 1s. per month, this production should succeed.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, 14th. The President, Major-General Waterhouse, in the chair. Mr. F. Martin Duncan gave a lecture on "The Applications of Photography to Investigations in Natural Science," in which he demonstrated rather than discussed the immense value of photographic record in the study of natural history. His lecture, in other words, was a talk on many interesting subjects of the animal and vegetable kingdoms, studied and photographed by himself during the past twenty years. The growth and fructification of plants, the study of micro-organisms, no less than the domestic amenities of the octopus and the blood-curdling devils of the insectivorous plants, were made the subject of a most fascinating discourse, illustrated with a series of lantern slides, which in no single instance failed to illustrate the lecturer's words. Mr. Duncan stated that he had devised a method of photographing minute transparent bacilli under the microscope, which dispensed with the drastic processes of heating and hot staining, by which the structure of the objects was probably greatly altered. He exhibited a specimen slide, wherein each bacillus rod was seen to contain certain cells and other structure; but he gave no details of the method.

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.—A meeting of the General Committee was held at 51, Baker Street, W., on Friday, November 15. Present, Messrs. F. A. Bridge, A. Ellis, S. H. Fry, H. E. Hull, M. Jaccotte, A. Mackie, H. S. Mendelssohn, D. Procter, E. Scamell, R. Fellows Willson, and P. Lankester (Tunbridge Wells). Mr. Alfred Ellis, Past-President, in the chair. The adjourned discussion took place upon the certificate scheme. The fact that members in advertising for assistants rarely think to notify that certificated assistants would have the preference was commented on, and it was decided to take all available means of reminding them of their duty in this direction. With a view to elicit the opinions of assistants themselves as to any desirability of modifying the terms or conditions of the granting of certificates, it was decided to write to all those assistants who had applied for prospectuses and had not subsequently taken up certificates to enquire the reason of their not proceeding further, and to invite suggestions for making the conditions generally acceptable. The Assistant Secretary reported that a dispute between a member and a firm of manufacturers of apparatus had been settled by the Hon. Secretary in a manner satisfactory to both sides.

PHOTOGRAPHIC CLUB.—On November 8 Mr. A. Bedding gave an illustrated lecture on "The Tower of London" to the members of this club. His views included many unfamiliar parts of the Tower. On November 15 the annual supper was held at the headquarters, Red Cross Hotel, Paternoster Square, E.C.

HULL PHOTOGRAPHIC SOCIETY.—Mr. T. T. Dyson gave a lecture on "Enlarged Negatives" to the members of this Society, at the rooms in Gray Street, Hull, on Thursday of last week. The lecturer said that before making an enlargement of any kind it is as well to decide what part of the original negative to include in the

finished print. A very convenient method of dealing with this operation was (after making a trial print in any process most convenient) to take a pair of right-angular masks cut out of a piece of flat, stiff paper, and these may be adjusted over the print until the most pleasing result has been obtained. The masks are really in appearance like the letter L, one being reversed so as to form a square frame, the opening of which can be varied. The paper should be, say, $1\frac{1}{2}$ in. to 2 in. wide, and the actual size of the letter 3 in. to 12 in. if for half-plate negatives. When it had been finally decided what part of the original photograph had to be included in the finished picture, the next step was to mark off the negative, so that only the selected portion might be printed on the transparency. This should always be done, as it went a long way towards making the finished result either a success or a failure. The next step was to polish the surface of the negative with a piece of soft rag moistened with methylated spirit, and carefully rub over the film until its surface became bright and smooth. The metal-polish reducer could be used for the same purpose in the same way (finally removing the grease with a piece of rag moistened with benzine), but it acted very much quicker, and consequently required more attention. The idea was to clean the film and not reduce it, continuous rubbing would bring about—both being often used for optical reduction. The metal polish-reducer is made up of a 2d. box of Globe Metal Polish, 2 oz. of olive oil, and 2 oz. of Terebine, the whole mixed together into a thick cream and filtered through a piece of fine muslin. The object of polishing the negative and transparency was to remove or reduce the granulation (so often present upon the surface of the gelatine) to a minimum, which, if allowed to remain, would enlarge, and so show upon the finished picture. A suitable transparency for enlarging from should contain all the gradations that could be seen in the original negative; no part should be clear glass, and yet the deepest shadows should be sufficiently transparent to allow the light to pass through and impress the plate before the other parts have gone too far. The lecturer preferred a slow, ordinary plate for the transparency, because it could be treated locally both by chemical and mechanical means, also because by varying the exposure and the developer it was possible to get soft results from hard or contrasty negatives, and so it was not difficult to get suitable transparencies from negatives of various printing qualities. The former must be soft, and contain all the gradation seen in the original, and not of the lantern slide type, as they were not suitable to enlarge from. The transparency could be made by contact or by projection, the latter being favoured. It was both convenient and economical when commencing to sacrifice a plate for the purpose of ascertaining the correct exposure, by giving a number of same in strips, covering up the negative with a piece of card, and giving first five, then ten, fifteen, twenty, and twenty-five seconds. A non-staining developer (1 part sodinol and 30 parts water being recommended for the transparency) should be used, and mix sufficient for two plates—the trial and the final—so that both will be developed in the same strength and temperature. From the transparency thus secured the enlarged negative could be made in the usual way, observing the same precautions.

The report for session 1904-5 of the Dundee and East of Scotland Photographic Association, which has been put in the hands of the members, states that a successful year has been concluded. Over 500 negatives had been selected in the survey department as suitable for the work, so that the total number of prints in this section was over 1,500. The Association was indebted to the Town Council for a second grant of £50, and an application for a similar sum to admit of the work being carried on had been sent in. Considerably more than £100 had already been expended, and it was calculated that a further

sum of £100 would be required to complete the work. During the year the membership had increased from 142 to 150.

WHITBY CAMERA CLUB.—The eighth annual meeting of this Club was held on Friday evening, November 10. The report showed the Club to be financially sound, self-supporting, and with an increased membership. The following officers were elected for the ensuing year:—President, William Brown; Vice-Presidents, John Bruce and G. S. French; Hon. Critic, F. M. Sutcliffe, F.R.P.S.; Hon. Lanternist, E. Hall; Hon. Assistant Lanternist, H. A. Burnell; Hon. Secretary, Woodhouse Parkinson, Ocean Road, Whitby.

THE FEDERATION OF THE PHOTOGRAPHIC SOCIETIES OF NORTHUMBERLAND AND DURHAM.—A meeting of the Council of this Federation was held in the rooms of the Literary and Philosophical Society, Newcastle-on-Tyne, on Wednesday, November 8. Mr. W. S. Corder was elected President. The Secretary reported that the Federation consisted of fourteen Societies, with a membership of over 800. A lecture syllabus had been sent out to the various societies. It was decided that the annual re-union this session take the form of a dinner, to be held in Newcastle early in the next year, when one of the leading photographers of the country will be invited as guest. A lantern slide competition will be held on similar lines to the one last year. Mr. Arthur Payne, F.R.P.S., founder of the Federation, whose efforts are largely responsible for the flourishing condition of the same, was elected a life member of the Council. A new society, the Dudley and District Camera Club (Northumberland) was admitted to the Federation. The Hon. Sec. is John B. Scott, 1, Bedford Place, North Shields.

ST. ALBANS PHOTOGRAPHIC SOCIETY.—Lecturing on the 10th inst. on "Velox and its New Applications," Mr. A. W. Green described the varieties of the Velox paper suited for different classes of negatives, and introduced the "Nobra" developer for the production of glossy prints free from markings. He concluded by giving the following as toning formulæ which were found satisfactory with Velox:—(1) The copper bath of Mr. Fergusson. It is the most satisfactory of the one-solution toning baths, as the results are moderately lasting, but the colour, as a rule, is inclined to a red rather than a sepia: A.—Copper sulphate, 30 grains; potassium citrate neutral, 120 grains; water, 10 ozs. B.—Potassium ferricyanide, 25 grains; potassium citrate neutral, 120 grains; water, 10 ozs. Mix in equal parts and immerse the print. The colour quickly becomes warmer in tone, and may be removed whenever the colour desired is secured. A bright red can be obtained with this formula. (2) A "Sulphide" toning method, one based on the original formula of Mr. Blake-Smith. In this process the prints are first bleached in a mixture of iodine and potassium iodide, and then darkened by plunging into a solution of sodium sulphide. The drawback here, in the case of Velox, is that with the iodine bleaching process there is a decided tendency to staining. In place of it is used a mixture of ferricyanide and Bromide of potassium. The formula recommended is as follows:—A.—Potassium ferricyanide, 1 oz.; water, 9 ozs.; bromide of potassium, 30 grains. B.—Sodium sulphide, 1 oz.; water, 15 ozs. This solution will keep fairly well, and is easy to make up. The procedure is very simple and exceedingly fascinating. The prints, which should be either very well washed or treated with hypax or some other hypo-eliminator, are placed in the bleaching bath, in one minute or so the image is almost completely bleached away, now rinse in water and place in the sulphur bath. The print immediately assumes a rich sepia tone without staining of any sort. A few minutes' washing completes the process.

WATFORD PHOTOGRAPHIC SOCIETY.—The following have been elected officers for the current year:—President, H. Snowden Ward, F.R.P.S.; vice-presidents, Lady Ebury, Dr. A. E. Cox, and C. R. Girardot; Committee, Miss Kate Smith, Dr. C. H. Hall, M. Bate-man, J. Cullen, H. Langford Lewis; hon. lanternist, F. D. Ogden;

hon. treasurer, C. E. Head; hon. secretary, C. J. Trevarthen, Ashcroft, Bushey Hall Road, Watford.

EDINBURGH PHOTOGRAPHIC SOCIETY.—At the monthly meeting of this society on Wednesday of last week, the Rev. H. N. Bonnar gave a lecture on "Some Methods of Photographing Wild Birds." The lecturer dwelt on the necessity of knowing or learning the habits of birds, how to distinguish their eggs, where they usually nest, and how long the eggs take to hatch out, together with the habits of the young ones, whether they are able to run about the first day, or whether they need be nursed and acquire strength, etc., so that proper precautions might be taken to come at the correct time to get a successful photograph. Emphasis was placed on the absolute necessity of using the very fastest plates procurable, then the most suitable camera, and an account given of the different methods of making the exposure, such as long bulb and tube focal plane, electric release, etc. He emphasised the necessity of disguising the camera with suitable foliage to make it appear as like the surroundings as possible, and counselled making all preparations, such as erecting tripod, etc., as far away from the scene of action as possible, to avoid disturbing the birds; and, above all, and through all the lecture, ran the one cardinal virtue—patience. He concluded by showing a large number of good slides of wild birds and their various haunts, some of the plates having been taken by the bird itself actually releasing the shutter by an ingenious arrangement of straw and twine.

LEEDS PHOTOGRAPHIC SOCIETY.—On November 7, at the Law Institute, Leeds, Mr. Harry Wade gave an interesting demonstration of Oil Printing before the members of this society. The lecturer said the process depended upon the repelling action that a moist film of chromated gelatine exerts towards oily pigments or inks, which action becomes modified by exposure to light, the parts most affected acquiring an affinity for the ink in direct proportion to the light action. Paper is coated with hard gelatine, sensitised with potassium bichromate, dried, printed in daylight, washed free from bichromate salt, and then "rolled up" with printer's ink. Although single transfer paper has been recommended, Mr. Wade deprecated its use as the gelatine is over-hardened; he preferred to coat his own paper. A stout paper should be chosen; thin material would not stand the rough usage the print has to undergo while wet; a smooth-surfaced cartridge answers well, cut a little larger than the print required, to allow handling when inking, as the roller has a tendency to pick it up. It is coated with a hot 10 per cent. solution of hard gelatine, either by floating or flowing. The demonstrator adopted the latter method, supporting the paper on a sheet of glass, pouring a pool of hot gelatine in the centre, tilting until the paper was covered to the edges, and then pouring off the superfluous solution, just in the same way one would varnish a negative. Dry paper may be coated in this way, but it is better to damp it first, as in the former case the inking roller has a tendency to pick up the gelatine from its support. The coated film should be thin, otherwise the gelatine swells too much in the high lights, and there is a difficulty in getting contact with the finer details when rolling up. Mr. Wade instanced the branches of trees against a blank sky, which become recessed and do not receive their due proportion of ink. The film is allowed to set, then the paper hung up by a corner to dry. It is sensitised by immersion in a 5 per cent. solution of potassium bichromate for two or three minutes—stronger solutions do not seem to influence the results—and again dried. The printing speed of the paper is rather quicker than P.O.P., a decided advantage in winter. A thin negative is required, full of detail and gradation in the high lights, as one which would give a fair result on bromide paper. The paper should be exposed until the details in the high lights show faintly, a little experience, as

with platinotype, which it resembles, will help to gauge the correct depth. The best results are obtained on paper freshly sensitised—within 24 hours—although it may be kept coated with the plain gelatine for any length of time. The print as it comes from the frame is washed in cold water for half an hour until the yellow colour of the bichromate is discharged. It can either be inked up at this stage or dried and worked up afterwards, at convenience; in the latter case it will require a thorough soaking in warm water to saturate the gelatine, before inking up is commenced; the results are not technically so good as by the former method. The originator of the process recommended solid oil colours, but the demonstrator found ordinary letterpress inks equally good. In using solid colours, the outer surface should be scraped away and the soft interior worked up on a glass slab with a little turpentine to the consistency of a thick cream, finally distributed evenly with a roller. To apply the ink Mr. Wade used two rollers, one of large, and the other small, diameter, made of gelatine; also an ordinary rubber squeegee. The damp print—wiped to remove excess of water—is rolled with the roller until inked all over; on continuing to roll the ink lifts somewhat from the high lights, and the picture begins to appear. By using the smaller diameter rollers the ink is picked up more quickly. The process of applying and removing the ink alternately allows the operator to build up the desired effects, heavy pressure giving strength to the prints. The image can be removed at any time by a rag soaked in turpentine, and a fresh start made. New gelatine rollers are very tacky, picking up too much ink; this can be remedied by rolling in powdered alum, which hardens the surface. If the print will not take up the pigment, is a sign of under-exposure or too thick an ink; should it take the colour all over and refuse to give it up, then over-exposure, or too thin an ink is the cause. Mr. Wade successfully manipulated several prints, and also passed round examples in various colours, whose technical qualities were much admired, resembling carbon prints very closely.

CATALOGUES AND TRADE NOTICES.

A CATALOGUE of Mr. F. E. Ives' optical specialties reaches us from his sales agent, Mr. Albert B. Porter, 324, Dearborn Street, Chicago, U.S.A., and is a pamphlet which will probably be welcomed by those occupied with colour photography. It lists the prices of the Ives' new replicas of diffraction gratings, spectrographs, etc. Mr. Porter will send it free of charge.

WE have received a couple of well illustrated lists of lanterns and accessories and a series of "chic" Christmas photographic cards from Kodak, Limited. A postcard to 57-61, Clerkenwell Road, E.C., will bring a copy of each.

FROM Mr. Samuel J. Beckett, of 20, Baker Street, W., we have received a very complete list of lantern slides for hire. These slides embrace a wide range of subjects for travel-lectures. Most of the countries and capitals of Europe are represented, and readings are supplied to go with the different series. A new lecture on Norway sent for our inspection is representative of the other readings. It is concise and descriptive, is in notebook form, folding from the top, and it is printed on one side only of the page in bold type, so that the matter can be easily followed in a dim light, and, moreover, the page from which one reads remains always in the same position. The lantern list also contains some excellent "pointers for lecturers." Every amateur lantern lecturer should get a copy.

EXHIBITION prospectuses have been sent us from the Boston Camera Club (Hon. Secs., H. M. Hames and R. W. Halliday, 65, West Street, Boston, Lancs.), the Watford Camera Club (Hon. Sec., E. H. Jackson, 100, High Street, Watford), and the Lancaster Photographic Society (Hon. Sec., R. T. Simpson, 10 North Road, Lancaster).

Commercial & Legal Intelligence

No Case Made Out.—At Cardiff Police-court on Saturday last Alfred Williams was charged on remand with obtaining money by false pretences from Charles Shapcott, Emily Bryant, and Bessie Bryant. The allegation was that prisoner had been employed by Mr. Ballard, a photographer, to get orders. He obtained orders from the parties named in the charge, and received small sums of money on account, but he had not handed over the orders with the money. Prisoner questioned the witnesses with some astuteness to show that he had not acted fraudulently, and the magistrates decided that no case had been made out, and discharged him.

Theft of "Sticky-Back" Tickets.—Frank Chard, aged fourteen, was charged, on remand, at the Bristol Police-court, with stealing a number of receipt forms, value 5d., the property of H. O. Seaman, photographer, of 27, Castle Street, and with obtaining by false pretences 1s. from Mary Ann Burge, of 2, Goodhind Street, and 8d. from Mary Ann Johns, of 2, Gloucester Street, St. Jude's. Mrs. Burge stated that Chard asked her to buy some tickets by which she would be able to have her photograph taken at half-price—twelve "sticky-backs" for sixpence instead of a shilling. She understood the boy obtained a commission, and bought two tickets. On going to Mr. Seaman's she found the tickets were of no use. Mary Ann Johns said she bought three tickets from the boy for 8d. The photographs, she understood, were 3d. a dozen. An assistant to Mr. Seaman stated that the tickets were taken from the counter when witness and Mr. Seaman were absent. About twenty tickets from two stolen books were presented. No canvassers were employed. The boy pleaded guilty, and said he was sorry and did not know what made him do it. The remaining tickets were found at his home, 6, Lower Castle Street, and accused had given a man 6s. to keep for him. He had been discharged from two situations on account of dishonesty. The Bench decided to send the lad to Kingswood Reformatory for five years.

Re John Wm. Calvert, of 58, Stonefall Avenue, Starbeck, and carrying on business at Stonefall Terrace, Starbeck, and 16, Chapel Street, Harrogate.—The above-named debtor appeared for his public examination at the York Bankruptcy Court on Friday, before the Registrar. The statement of affairs filed by the debtor disclosed liabilities amounting to £104 16s. 10d., and a deficiency of £91 12s. 3d., the assets amounting to only £13 4s. 7d. "Heavy rents and rates, falling off of trade, and some bad debts," was given as the cause of the failure. In answer to questions put by the Official Receiver, debtor said he began business at Boroughbridge as a painter and decorator about nine years ago, and continued for three years, afterwards removing to Starbeck. The latter business was successful for the first two years, but declined very much in the past four years. It was his venture as a photographer at Chapel Street, Harrogate, that contributed the most largely to his insolvency, the rates and rents being very heavy. He had hoped to sell the business, but had not done so. The examination was adjourned for formal completion.

An application for discharge from bankruptcy was made before his Honour, Judge Parry, at the Manchester County Court, last week, by Franz Baum, photographer, of Manchester and Bolton. It was reported by the Official Receiver that the receiving order was made on a creditor's petition on November 26, 1904, and the liabilities proved amounted to £509. No dividend had been paid, and the assets were insufficient to meet the expenses of the bank-

ruptcy. The Official Receiver submitted that the bankrupt had omitted to keep proper books of account, that he had contributed to his bankruptcy by rash and hazardous speculations, and that three months previous to his bankruptcy he gave undue preference to one of his creditors. The bankrupt contended that he had not wittingly committed any offence against the Bankruptcy Act. His Honour suspended the discharge for three years.

BARRAUDS, LIMITED.—This company has been registered with a capital of £1,500 in £1 shares, to acquire and carry on the business of a photographer, and dealer in works of art and vertu, etc., now carried on under the style of Philip Barraud, at 92, Bold Street, Liverpool, and to adopt an agreement between Philip Barraud and L. Dedwydd. There will be no initial public issue. The qualification of the directors is £10 in shares, and the first directors are to be P. Barraud and L. Dedwydd. The registered offices are at 92, Bold Street, Liverpool.

H. A. WEST AND CO., LTD.—Registered November 2. Capital £1,500, in £1 shares. Objects: To take over the business of a chemist and druggist carried on by H. A. West at 15, St. Stephen's Road, Norwich, as Lowe and Co., and to carry on the same and the business of opticians, dealers in photographic and scientific apparatus and materials, etc. No initial public issue. Registered office, 15, St. Stephen's Road, Norwich.

An Impudent Theft.—At the Guildhall Police-court, on Wednesday last, George East, of no occupation, was charged, before Sir John Bell, with wilfully smashing a plateglass window at Messrs. Beck and Co., Limited, opticians, of Cornhill, doing damage to the extent of £4, and, further, with stealing a number of nautical instruments from the window. A constable on duty in Cornhill that morning saw the accused take off one of his boots, and with the heel of it smash the window. Putting his arm through the hole he abstracted several of the instruments, and was running away when the officer stopped him. The prisoner was remanded.

At the Gloucester County Court on Tuesday of last week, Joseph Baggett, photographer, of Conduit Street, Gloucester, made an application for an administration order, which was granted.

A FIRST meeting of creditors of William Marsden Harrison, photographer, Falmouth, Truro, Redruth, and Helston, was held on Monday of last week at Truro. Debtor's statement showed gross liabilities £2,063, of which £611 was expected to rank, and an estimated surplus of £1,122. His assets included property £586, book debts estimated to produce £150, and surplus from securities in hands of creditors fully secured £159. He attributed his failure to pressure by creditors, general depression in trade, and the great reduction in the sale of photographic views caused by publication of picture postcards. The Official Receiver, in his observations, said debtor filed his petition in consequence of pressure by two trade creditors, who issued writs against him for £84 and £73 respectively. He commenced business in Falmouth in 1876, and in 1879 filed a petition for the liquidation of his affairs. His liabilities were then £887, and his assets were estimated at £620. A first and final dividend of 1s. 5d. in the £ was declared in 1880, and he obtained his discharge in 1881. The following year he again started business at Falmouth with a free capital of about £50 in cash, and continued in business there and at the branch establishments until the present receiving order was made. The assets included £500 expected to be derived under the will of his deceased mother. The surplus of £1,122 over total liabilities appeared to be somewhat uncertain. The debtor had not been adjudicated a bankrupt, and the business had been carried on with the approval of the principal

creditors until that date with a view to disposing of it as a going concern. He estimated his profits during the past three years from the photographic business at from £300 to £400 a year. The meeting approved the course adopted by the Official Receiver, passed a resolution in favour of the adjudication of debtor as a bankrupt, and appointed a trustee and committee of inspection, and decided to retain the present staff, as well as the service of debtor, the latter to receive £3 a week.

News and Notes.

B. J. EDWARDS and Co.—We are pleased to hear that this old-established firm is again coming to the fore in the manufacture of plates and films, and the fact that Mr. Edwards himself is now personally taking an active part in the firm's productions can be regarded as a contributory cause of revived activity and a guarantee for future excellence. Mr. J. W. P. Rawlins is the general manager, and he will see that everything on the business side is promptly and efficiently attended to.

At the Third Scottish National Photographic Salon, to be held at the Victoria Art Galleries, Dundee, in 1906, the walls are to be hung with a representative collection of Mr. Evan's work; while Herr M. Matthias, a German worker of note, is also arranging for a special display. No doubt those invitation collections will be a great treat to the Scottish pictorialists who can visit the Salon at Dundee.

THE Cripplegate Photographic Society.—This flourishing City Society, with its headquarters at the handsome Cripplegate Institute, Golden Lane, E.C., only needs to be a little better known to local and other photographic workers to become one of the foremost societies of its kind in the London area. Possessed of ample accommodation for its meetings, and a permanent and well-equipped enlarging and dark room, the members must find little to grumble at in return for their subscription. Grumbling is the prerogative of every member of every photographic society, but in the case of the Cripplegate Society the most inveterate grumbler must find his occupation gone, especially when he contemplates the list of fixtures that the indefatigable Hon. Sec., J. B. Parnham, has got together for the forthcoming winter session. "Gum Bichromate," by J. C. S. Mummery; "Enlarged Negatives," by Bertram C. Wickison; "Intensification and Reduction," by J. McIntosh; "The Hand Camera," by W. L. Wastell; "Figure Photography," by E. H. R. Hillsworth; "Retouching," by H. Gordon Stollard; "Photography with the Microscope," by J. I. Pigg; "Pictorial Photography," by A. Horsley Hinton; "Marine Photography," by F. J. Mortimer; and lectures by Alex. Mackie and R. Child Bayley are among the items in the programme, which is fully filled until May next. The "Members' Book," in which full particulars of the Society are contained, is one of the neatest and handiest of the many winter programmes and year-books we have seen this season. It is compact in size, and, in addition to the information mentioned, has a good amount of space for notes and diary. The Hon. Sec. will be pleased to forward particulars of membership, etc., on application to him at 5, Reighton Road, Upper Clapton, N.E. The annual exhibition, which will be held in the large hall of the Institute is fixed for March 12-15, 1906, and entry forms will be ready shortly.

MR. THOMAS G. AMES (formerly representative of Messrs. B. J. Edwards and Co., Ltd.) is now representing Messrs. Elliott and Sons, of Barnet, in the North of England, Scotland, and Ireland.

BORDER Occasionally seen between Light and Dark Regions on Photographic Plates.—Two correspondents writing to "Nature" on

this subject, do not entirely concur in the view of Sir Oliver Lodge (reprinted in our last issue). Professor F. J. Allen writes:—The reason mentioned by Sir Oliver Lodge for the border seen between light and dark regions on photographs is not the only one. In the denser regions of a negative the developer gets more exhausted or restrained than in the thinner regions, and this affects the adjacent parts. At the junction of a dense and a thin area the edge of the thin part is made thinner by the restraining compounds (bromide, oxidised pyrogallol, etc.) derived from the denser part, while, on the contrary, the edge of the denser part is made denser by the less exhausted developer flowing from the thin area. This effect is apt to be the more marked when the developer is already well restrained, as by staleness or the addition of much bromide. R. Child Bayley says that the explanation does not take into consideration the following facts: (1) The "perceptible difference in thickness" between the acted-on and unacted-on portions of a negative is only perceptible to our unaided senses when certain developers are employed containing substances which act powerfully on the gelatine. Most modern negatives certainly have no perceptible difference in thickness, certainly not enough difference to give rise to so marked an effect as that referred to. (2) The difference in thickness is most marked in the "carbon" transparencies from which many enlarged negatives are made. Here it can be both seen and felt; in the other case it cannot. We might therefore expect this cylindrical lens effect to be most marked when using such a transparency, but the careful comparison of a number of enlarged negatives made in these two methods reveals not the slightest difference between them. In my own mind I have always accounted for the phenomenon in the following way: The sensitive film ordinarily can only be approached by the developer from its outward face, hence the action over an area where the light action has been the same is uniform. But if that area is bordered by one where there has been little or no light action, the developer absorbed by such parts is not spent in doing any or much work in those parts, and, so far as any lateral diffusion is concerned, is practically fresh developer. Hence the borders of an exposed portion, where it comes against an unexposed portion, are attacked by fresh developer diffusing both from the front and from the unexposed part, and we should therefore expect to find a border line of greater density there, as, in fact, we do. For a similar reason we should expect to find a less dense line on the border of the more transparent portion, as is the case, though it is not often so noticeable as the former. That this is the true explanation is, I think, made manifest by the fact that the line in question can be quite easily distinguished on plates exposed in Spurge's actinometer, where there is certainly no opportunity of a "cylindrical lens effect," and especially when development has been pushed far.

THE Worthing Camera Club's new rooms in Liverpool Terrace were opened by the president, Colonel A. Henty, last week. A dark room has been fitted up, and an enlarging apparatus provided.

THE Lancashire and Cheshire Photographic Union.—As previously announced in these pages, a Photographic Union has been in course of formation for the societies in the counties of Lancashire and Cheshire. The matter has now been finally settled, and the following particulars are to hand from the hon. sec.:—Officers for 1906—President: Dr. C. Thurston Holland; vice-presidents: Rev H. W. Dick (Manchester), Dr. Brennan (Stockport), Dr. Crump (Burnley), T. Lee Syms (Leigh). Lantern Slide Section—Hon. sec.: T. Hudson, 6, Rigby Street, Nelson. Print Folio Section—Hon. sec.: Dr. A. T. Lakin, Lightbowne Road, Moston, Manchester. Jury of Selection for Union Prints and Slides: Dr. C. T. Holland.

Rev. H. W. Dick, Messrs. S. L. Coulthurst, C. F. Inston, J. J. Rothwell, and F. Whitaker. Judges available for Union Societies' Competitions and Exhibitions: Dr. C. T. Holland, Rev. H. W. Dick, Dr. Crump, Dr. A. T. Lakin, Dr. Ellis, Messrs. S. L. Coulthurst, F. Anyon, T. Lee Syms, J. W. Wade, A. E. Bellingham, C. F. Inston, T. Glazebrook, J. Shaw, Tullock Cheyne, and A. W. Cooper. The societies comprising the Union are:—Accrington Photographic, Ashton-under-Lyne Photographic, Barrow-in-Furness Photographic, Birkenhead Photographic, Blackburn Photographic, Bolton Photographic, Bootle Photographic, Burnley Camera Club, Bury Athenaeum Photographic, Colne Camera Club, Crompton Camera Club, Darwen Photographic, Duckinfield Photographic, Everton Camera Club, Leigh Photographic, Liverpool Photographic, Manchester Photographic, Nelson Photographic, St. Helens Camera Club, St. Mathew's (Bootle) Camera Club, Sale Photographic, Salford Park Photographic, Simpson Memorial Camera Club, Southport Photographic, Stockport Photographic, Wallasey Photographic, Walton Photographic, and Widnes Photographic. The Hon. Business Secretary and Treasurer is W. Tansley, 22, Chapel Place, Liverpool.

A NEW KNIGHT.—We note the name of Edward Cecil Hertslet among the recipients of Birthday Honours. He has served the Foreign Office for over 37 years, and has been British Consul at Antwerp and Havre. Interest for our readers in the new knighthood centres in the fact that Mr. Hertslet was British Member of the International Jury Photographic Section at the Paris Exhibition.

THE Second American Salon.—We learn from an American contemporary that the standard of work submitted to the jurors of the forthcoming American Salon is very high, and superior to last year's exhibit. This, together with the large entry received, speaks most encouragingly for its success. The work submitted to various centres is now en route to New York.

DURING the last few days many suggestions have been made that the "Venus and Cupid" by Velasquez, which is now on view at Messrs. Agnew's gallery, should be added to the excellent series of works by that master in the National Gallery. It can hardly be said that there is any chance of anything resulting from these suggestions unless some wealthy art lover, or group of art lovers, can be induced to purchase the canvas and present it to the nation. The habitual parsimony of the British Government in art matters, observes the "Globe," makes it extremely improbable that the Treasury will respond to a request for the acquisition of a picture which certainly ought not to be allowed to leave this country. When great opportunities occur the National Gallery has to let them slip because practically it is supported by charity, and has to look to outside assistance for funds which will sufficiently supplement its inadequate grant to enable it to carry on its work with passable efficiency. The contributions of the charitable are hardly likely to put it in a position to secure a masterpiece by Velasquez which is coveted by the whole world.

THE thirty-fifth volume of the "Studio," which has just been published, is lacking in none of the characteristics which have made this magazine for some years past so conspicuously successful. One of the most noteworthy merits of the "Studio" has always been its consistency in advocating the claims to attention of all art that is correctly and sincerely original, and in this volume there is no sign of departure from a policy which is commendably enlightened and broad-minded. The articles included in it cover the widest possible ground, and sum up an astonishing number of phases of artistic activity, not forgetting photography; and the illustrations, always excellently reproduced, show well what is being done by art workers all over the world. The array of special plates in colour is an admirable feature of the publication.

Correspondence.

DEVELOPING P.O.P.

To the Editors.

Gentlemen.—I have been trying your formula for developing P.O.P. ("B.J.," October 20, p. 822). I find this gives a brown tone, but it may be that I did not use the right quantity of citric acid, as you do not give the quantity. I did not like the brown tone, so I tried the formula as follows, given in "Photography":—Metol $\frac{3}{4}$ grain, water $1\frac{1}{2}$ oz., glacial acetic acid 85 minims, solution of citric acid (96 grains to 1 oz.) 85 minims, solution of potass bichromate (10 grains to 1 oz.) 3 to 5 drops. The tone given with this is just like gold toning bath, but it takes a long time to develop, and the prints lose a lot in the hypo. Can you tell me how to quicken this formula without altering the tone? Also, is ten minutes in the hypo bath sufficient (hypo 3 oz. to pint)? I have a large quantity of P.O.P. postcards to turn out between this and Christmas. Can I develop these in large batches as with gold toning, or must they be done a few at a time.—I remain yours faithfully,

E. A. BARTLETT.

7, High Street, Leamington,

November 10, 1905.

[We insert our correspondent's letter here thinking that perhaps others who have experimented with P.O.P. developers may help him out of their experience. Cautious increase of the bichromate should quicken development, but will certainly affect the tone. We should advise reducing the citric and acetic acids instead. A ten minutes' immersion in the hypo is adequate. In regard to the development of postcards, our experience of every developer for the purpose is that the back of the print is discoloured, a defect of the process which matters nothing in the case of prints to be mounted, but unfits it for postcards.—Eds., B.J.P.]

DETAIL IN GUM.

To the Editors.

Gentlemen.—It has often been urged against the process of gum bichromate that it is incapable of rendering fine detail, requires a specially thin negative, and, apart from multiple coating, lacks depth and range from deepest shadows to purest high lights.

Your opinion, therefore, on the little prints enclosed, produced solely for this purpose, may prove of interest to your readers, for I have always contended that this method of single-coated printing is capable of giving as clean and sharp an image as any other matt surface process. The prints, all from plucky, sharp, fairly dense negatives, just such as many professionals aim at, and half a dozen other prints almost practically identical, were obtained at the same time with almost dreary monotony.—Yours, etc.,

J. PAGE CROFT.

Quadrant Chambers, Birmingham.

[The prints sent by Mr. Croft are from negatives of black-and-white line sketches, and are excellent reproductions of this class of original.—Eds., B.J.P.]

PLUMBING FOR PHOTOGRAPHERS.

To the Editors.

Gentlemen.—Mr. W. Foster Brigham's article on "Plumbing for Photographers" is interesting, but his idea in the matter of the syphon is very crude. He says, in effect: "Put one end of a length

of tubing into the sink, let the other end hang down outside over a pail, then put this end into the mouth—or someone else's mouth—and suck out the air." If I may be allowed to say so, a very dirty, unhealthy, and unnecessary proceeding for one's own or anyone else's mouth. Of course, the proper way is to immerse the whole of the tubing in water, close the ends under water, some assistance being necessary with thick tubing; one end, the lower, must at all events be closed. The elongated portion may now be removed to any convenient place lower than the sink, and on unclosing the ends (one of which will be held or secured to the sink) the water flows and empties.—Yours truly,

November 11, 1905.

J. PIKE.

THE PERMANENCY OF MATT COLLODION PRINTS.

To the Editors.

Gentlemen,—Some time ago, perhaps a year, or even two, not being able to go to the meetings myself, I sent to the Secretary of the London and Provincial Association a sample, or samples, of fading of commercial collodion chloride paper, with the request that they should be shown at a meeting and returned to me. Whether they were shown or not I have not heard; they never came back to me. They were finished with all the care I could bestow upon them. There was no mistaking the prints had gone, in quite a short time. There is no need for surprise that some samples of C.C. paper should be so fugitive when we consider the composition they are coated with and the quality of the support. I have in my possession C.C. prints made by Mr. Bruce, of Duns, about twenty-five years ago, they were—he informed me at the time—made upon paper from abroad. They are as good now as they were when new. But they are glossy (there is no difficulty in matting a C.C. glossy paper, simply requires putting down on "smoothed" opal). It it the attempt to matt C.C. and sell it at a price comparable with P.O.P.—the great yearning for anything and everything that is low priced—that has brought about this cry against the process. Collodion paper cannot be made good at a very low figure. Moreover, one must not forget that it is unfair to condemn a process because perhaps only one or two samples of commercial papers are faulty.—Yours truly,

ALF. J. BROWN.

Walthamstow.

November 15, 1905.

To the Editors.

Gentlemen,—Referring to the discussion on this subject which is going on in your columns, I may mention that the "Aristo Manual" issued by the American Aristotype Company goes very fully into the manipulation of C.C. papers, and fully clears up all the points mentioned by your various correspondents. I have no doubt that Mr. H. M. Fell, 57-61, Clerkenwell Road, E.C. the representative of the company in this country, will be pleased to send a copy to any inquirer.—Yours faithfully,

November 14, 1905.

KODAK, LTD.

pp. J. Brown.

To the Editors.

Gentlemen,—The trouble with C.C. papers complained of by the various correspondents under the above heading comes from several causes. Whenever yellowish spots appear in the prints after mounting—it may be the next day or some time after—in ninety-nine cases out of a hundred they are caused by the moisture not being thoroughly dried out of the interior of the mounts. When prints are supposed to be dry and are stacked up for spotting, and later placed together in packages, this moisture draws through the mass of mounts so stacked or placed in packages, and carries with it the impurities in the mount, the colouring matter of the mount, or

acid generated by damp paste. These various impurities, carried through the prints, attack the image, more often in spots, but sometimes the whole print is affected. The cure for this trouble is easy and absolutely certain.

Firstly, never lay prints flat on a table to dry after mounting, but always place them in a rack so that the air can get to the back as well as the face of the prints.

Secondly, when surface dry, give them the same chances as any other silver prints, and run them through a hot burnisher with thin smooth cardboard to protect the face of the print from a polishing roll. Have the burnisher hot, not warm. This will heat the mount and thoroughly dry out all moisture from the interior of the same, and will also shape the card much better than a cold burnisher. Those who use a "Globe" enameller can easily take off the top back cog by unscrewing the centre screw of the same and slipping the cog off. When this is done prints can be run through the burnishing rolls without any cardboard protection as both rolls will then run alike and will not burnish.

How long do you think it would be before P.O.P. or albumen prints would show this trouble if they were not burnished? Ever quicker than C.C. In burnishing these other papers the mount is heated and all the moisture is thereby dried out. A great many people do not realise this, but they will readily bring it to mind when they stop to think how often apparently dry mounted prints on being run through a hot burnisher for the first two or three times, become quite soft, and as the burnishing is continued the mounts become more solid and firm. In other words they are being dried. If this plan be pursued, and the mounts are once thoroughly dried, there will never be any further trouble owing to yellow spots from this cause.

Yellow spots can also come from leaving prints in damp blotters or stacking prints in blotters and leaving them there for some hours, but spots produced in this way are very often much smaller than those caused by moisture in the interior of the mount.

When wishing to dry C.C. prints before mounting, squeegee the water out, lay them out on clean dry blotters, place clean blotters over the face of them, and lay them out to dry. Never place two or more lots of blotters with prints between them on top of each other. The trouble generally comes from piling a number of blotters containing prints on top of each other. The effect of this is that any acids, bleaching chemicals, or hypo in the blotters are released and disseminated through the mass, affecting the prints lying in between. The same troubles will likewise happen to albumen prints, as any old worker knows full well. All blotters, after being used, should be hung up by clips on a line to dry before being stacked away for use again.

In reading the letter from "Othello," I must differ from him as to the difference in the climatic conditions in America and England, as in certain portions of America where C.C. paper is used and worked most successfully, i.e., in the New England States, and also in Oregon on the Pacific Coast, the amount of moisture in the air is fully as great as in England, and in the latter place on the Pacific Coast I am inclined to think it is greater, as all houses with wooden instead of tile roofs will have a very heavy coating of green moss on them within a year or two of being built, from the amount of moisture in the air. C.C. papers will work in any climate, but are more specially suited to a climate like England, with considerable dampness; but ordinary precautions must be taken to thoroughly dry out the moisture in the mounts. If "Othello" will use the hot burnisher, as suggested, he will be free from most of his troubles with yellow spots.

The experience of Mr. Bertram T. Hewson I quite agree with. If care and cleanliness are used in working C.C. papers they will be found to be all that the manufacturers claim for them, and with-

out any exceptions as permanent as any other process with paper as a base for the emulsion.

C.C. is an ideal paper for the professional photographer, and the photographer or printer who learns to work C.C. and gives as much thought and care to it as he would to any other process will find it will repay him for all his trouble in certainty of result and beautiful effects.—Yours respectfully,

H. MATTHEWS.

November 14, 1905.

TRUMPETING!

To the Editors.

Gentlemen,—I have read with great interest in your pages a paper read by Mr. J. Burgess before the London and Provincial Photographic Association, and I am astonished that there is a photographic worker living who has so much brass in his composition. Gold and silver are the metals most associated with photography—"speech is silvern, silence is golden." Brass is associated with the trumpet and trombone, and all three are visible in this paper. Those of us who are scribes will highly value the appreciation Mr. Burgess gives us in connection with the honours done Dr. Maddox. Were all the people who helped in that matter—fools? Did nobody know beside Mr. Burgess what he (Mr. Burgess) had done? He says men are gullible, and he says that, too, now, when he tries to upset honour done another man. It is clear nobody knew anything but one man, and he never spoke—presumably. Surely proof could have been forthcoming if the wrong man was being honoured. Editors do not, as a rule, tell the man-in-the-street that they got certain copy because they were wanting matter to fill a certain space. And Traill Taylor was not a garrulous man in that way. He was a human like the rest of us, and he was an honest man, too. The aspersion Mr. Burgess makes surely was unnecessary. Of course, it is easy enough to go on and on when the first step is made. And so bromide paper was not invented by the inventor, but by somebody else. This, of course, may be true, but people are so gullible, so Mr. Burgess says. What one regrets to see in this is the I, I, I, of it. "I am the trumpeter." Mr. Burgess is, so he says, the inventor of a "new process for producing all the colours of Nature, in proper gradation, by mechanical means." We do not wish to miss this, even if it is not a photographic process, but hand finished, as some say. There are a lot of sceptics in the world though we are such a gullible lot.

O!

MAKERS' FORMULÆ.

To the Editors.

Gentlemen,—Can you inform me if photographic formulæ for developers are generally apothecaries weight or avoirdupois? I have just written to Elliott and Sons, and they reply that their formulæ are avoirdupois; Marion and Co., on the contrary, reply that their formula for P.S. plates is apothecaries. I need hardly point out to you that here lies a stumbling-block to photographers. As a matter of fact, I have used apothecaries' weight for all my formulæ.

I suggest to you it is a matter that the BRITISH JOURNAL should take up, and either get uniformity or an announcement published by the various makers.—Yours faithfully,

C. P.

November 11, 1905.

[We are afraid there is no prevailing custom. Our own preference is for the use in formulæ only of ounces (avoirdupois) and grains (solid measure), and fluid ounces and minims (fluid measure). A number of leading makers are fairly consistent in adhering to some such system as this, which gives a formula incapable of two different readings. In preparing the forthcoming "Almanac" for the press we have sought to safeguard every formula from misinterpretation, but the vagaries of formula-makers makes the task one of no slight difficulty.—Eds., B.J.P.]

Answers to Correspondents.

- *^{*} All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- *^{*} Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- *^{*} Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- *^{*} For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

A. Laurens, 10, Pollet Street, Guernsey. Photograph of Group of the Duke of Connaught, Generals Campbell and Leslie, Captain Campbell, Mrs. Campbell, Miss Campbell, Mr. Campbell, and Major Murray.

J. Bowe, Union House, High Street, Plumstead, London. Photograph of the Rev. F. Cowen.

P. Peters, 1, Bland's Cliff, Scarborough. Photograph entitled "A Wave that Stopped the Tram, Scarborough."

J. Weir, 9, Elliot Street, Hillhead, Glasgow. Photograph entitled "Taking the Bains to Weir's."

Salter & Sons, The Studio, High Street, Broseley, Salop. Photograph, Iron Bridge, Salop.

FLASHLIGHT.—I have had several photos to take at night, and every photo I take there is a shadow showing at the side of face. I am using the Todd-Forret magnesium flash lamp, costing 12s. 6d. I should feel obliged if you could tell me how I can avoid the shadow. I put the lamp on the camera. Should the lamp be direct in front, or at sides, or does it require more than one lamp?—F. MALTHOUSE.

You use the lamp in the very worst position for good portraiture, and the shadows you complain of are caused by the figures being too near the background. Two lamps are better than one, but as you are using only one, place it seven or eight feet up and three or four feet to the right or left of camera. In addition to this use a reflector of white paper or calico for the shadow side of the face. Do not include this in the picture, and arrange the light so that its direct rays do not impinge on the surface of the lens.

HIGHLAND LADDIE.—The two developers are quite different, and you had better make the solutions as directed for the latter (pyro-soda). Failing this you should use the stock pyro solution given in the forthcoming "Almanac," and suitable for either amonia or soda.

COPYRIGHT IN PORTRAIT.—I invited a gentleman to sit for his photograph, which he did. I did not charge him, but gave him a few copies. 1. Is the copyright mine, although I did not mention anything to him about it being my copyright? 2. Is it necessary to get a written statement assigning copyright to me? 3. As I understand it, I could not publish his portrait without his permission. 4. Can he issue it without mine? I may say that I have not registered it yet.—ENFREW.

1. Yes. 2. You should do so. 3. His permission is not required. 4. No. You should register the photograph, as you would be able to obtain penalties for any infringement before registration. See the article on "Photographic Copyright" in the forthcoming "Almanac."

A. A. A.—We should advise you to write to a few of the leading makers.

REMOVING SILVER STAINS.—Will you kindly state procedure for removing silver stains from negatives? I have a negative which is a particularly bad case, it was being printed in glossy C.C. paper, but was unfortunately left out and got wet, the

paper in consequence sticking to the negative, and although the negative was varnished, and it was at once put into spirit for the removal of varnish with the hope of saving the negative, it is found that the surface of the printing paper seems to have eaten into or combined with the film of the negative, leaving absolutely opaque patches.—H. W. B.

If the varnish has been entirely removed and the negative is perfectly dry, rub the stained portions with pumice powder, and then place in a bath of strong hypo. If this fails to remove the markings, wash and dry the negative and place it for ten minutes in potass. iodide solution (20 gr. per oz.). Wash and transfer to potass. cyanide solution (30 gr. per oz.) rubbing with cotton wool. The last named solution is very poisonous.

REDUCING HIGH LIGHTS.—Will you tell me of a satisfactory way of reducing opacity of high lights, such as windows, etc., which could not have possibly been blocked out during exposure? I find by rubbing down the parts with spirits that it is very difficult to get it all the same density; some parts being rubbed slightly more than others. Also, that if by using pyro-soda and hydroquinone developers more than once (say using 6 oz. of developer for three 12 by 10s) is it detrimental to the last plate developed?—A. E. H.

1. The best plan for you to adopt is the bleaching and re-development method. Immerse the negative in chromic acid 30 grains, potassium bromide 60 grains, water 10 ounces, and allow it to remain until the image is thoroughly bleached. Wash thoroughly for ten minutes, and proceed to develop with any clean acting developer, well diluted. If, after a few seconds' application, the plate is examined from the back, it will be seen that the whole of the shadow detail has been blackened, and the half-tones and high lights only partially so. Continue the action until only the halated high lights remain white, then plunge the negative into a strong hypo solution, which will dissolve out the unacted-on silver bromide and leave every portion of the window of a printable density. Experiment on useless negatives first, as experience is needed to tell exactly when to stop development, which can be conducted by daylight. 2 The pyro-soda should not be used for more than one plate. Hydroquinone developer may be used several times until exhausted.

TINTING PRINTS.—Please publish in next issue a cheap and effective compound for tinting gelatine prints, allowing that nothing is sufficiently permanent to stand sunlight for many months, such as aniline for colour, borax for adulteration, and gum to bind—soluble in water—DAUBER.

If you will look through the advertisement pages of this journal you will find several reliable series of photo-tints advertised, which should meet your requirements.

PERPLEXED.—There is no fault to find with your toning bath, but we should certainly advise the addition of $\frac{1}{4}$ oz. of liquor ammonia, 880, or $\frac{1}{4}$ oz. of carbonate of soda to every pint of your fixing bath; for, as you do not wash your prints prior to toning, there is some possibility of some acid, which is always present in the emulsion, being carried into it, and you would thus have a possible cause of fading. Your washing, however, is needlessly long, and to this we should ascribe the whole of your trouble. Doubtless you have the B.J. for March 31, 1905, if so, read the note on "Short versus Long Washing." Refer also to our issue for July 28, p. 583, "The Fixing and Washing of Prints." This last article particularly should cause you to alter your method of washing. Your mountant is a little too fluid, and if not kept well corked would be a probable cause

of trouble, as it would be liable to turn acid and attack the image. With regard to your lens query. The new lens you mention certainly covers the plate much better at a larger aperture; in fact we may say that it would cover at full aperture. It has also a longer focus, which is an advantage for cabinet work. The new lens working at $f/6$ is absolutely the same rapidly as the portrait working at $f/6$.

LENS QUERY.—What is the best kind of lens to use for general portrait work in a studio 21 ft. long by 12 ft. broad? I have a cabinet portrait lens by Grubb, of Dublin, but the focus is only 6 $\frac{1}{2}$ in., and I have the impression that I might work with a better lens. Would you advise the use of two lenses—one of a longer focus for single figures, and a shorter focus lens for groups, and if so what kind of lenses? I may say that I find no great depth in the focus, but no doubt that is the case with most portrait lenses. The lens is a very old one, and perhaps a more up-to-date lens would be advisable.—PORTRAIT LENS.

The most useful instrument for portraiture is the portrait lens, because it is so much quicker than any other form. The one you have is, no doubt, a carte, and not a cabinet lens, its equivalent focus is but 6 $\frac{1}{2}$ in. No portrait lens of that focus can be expected to cover the cabinet size. A lens of about 11 in. focus will require from 16 to 17 ft. between sitter and camera, and that would be the most convenient to use in a studio 21 ft. long.

A CORRESPONDENT writes:—"I shall be glad if you can tell me the name of the maker of the 'Midnight Sun' New Improved Photographic Arc Lamp (Patent)."

We cannot say; but will hand any replies on to the inquirer.

AMERICA.—We cannot say. Better address an inquiry to one of our American contemporaries, the names and addresses of which you will find in the ALMANAC.

J. H. E.—1. Albumen or P.O.P. 2. It is the usual method. 3. Nothing; dyes, more or less permanent, are selected. 4. No, but you can get a pamphlet from Jonathan Fallowfield.

S. WALES.—Try Jonathan Fallowfield.

VICAR AND SEXTON.—Kindly tell me who is the rightful owner of the following copyrights. The vicar has made copyright a photograph of his church, and wishes to assign it to me for work done. The sexton tells me he gave orders for the photograph to be taken, and he did so for the purpose of selling copies for the benefit of the church. He paid the photographer out of the money raised. Is not the vicar the rightful owner? The man is a servant of his, and work done for the church is the vicar's property.

The copyright belongs to the one who paid the photographer for taking the picture. If the sexton did that as a speculation of his own the copyright belongs to him.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

A Notable Demonstration at the RPS. Members of the Royal Photographic Society and their friends should look forward with interest to December 5, when Sir William Abney will give a practical demonstration of three-colour photography. It is certain that every one who was present when Sir William Abney exhibited a number of his results in three-colour at the New Gallery, will desire to attend the demonstration, at which Sir William will confine himself to practical ways and means. Not every scientific investigator of photography can claim any proficiency in practical photography, and anybody who may have thought that in Sir William Abney's case science outruns practice will be interested in witnessing his skill in that most delicate of processes—three-colour.

* * *

A Belated Suggestion. The handsome "Magazine of Fine Arts," which we received last week on the appearance of its first number, shows itself lamentably in the dark of what photography is doing. We find it advocating, apparently as something new, the systematic photography of objects of artistic and archaeological interest in the British Isles. "It is a little curious," it writes, "that the almost universal interest taken by present-day people in the artistic and archaeological remnants from past ages should not have suggested the advisability of some effort to provide future generations with things which would in the same way be interesting to them." And this after all the National Photographic Record Association has done!

* * *

Working Platinotype. It would be difficult to imagine more trying climatic conditions for working the platinotype process than those obtaining at the present time. The atmosphere is heavily charged with moisture, and negatives are cold enough to readily condense the moisture of a warmer air. One of the safest methods of daylight printing is to employ box-bottom printing frames with stout plate-glass fronts and rubber pads a size larger than the negatives in use, and to avoid opening the frames at all gauging the exposure to light by means of an actinometer. Of course it is only when these difficulties have been anticipated and provision made for this system of working that it can be employed when the exigencies of weather demand. In businesses where the amount of platinotype printing is considerable we think it would pay to fit up a single tube of the mercury-vapour lamp, arranging it vertically so as to hold the printing frames in a hexagonal stand around the tube. Quite a number of frames might be printed at the same time, and if the work were carried on in a dark room kept constantly warm and dry, uniformity of results is and increased output would soon repay the cost of the

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1906.

EDITED BY GEORGE E. BROWN, F.I.C.

The whole edition of 25,000 copies of the 1906 ALMANAC is now approaching completion, and its issue to the trade is a matter of a few days. As the orders already placed for the forthcoming volume show that the demand exceeds even that for previous years, the publishers request dealers and individuals who have not yet ordered to do so at once, otherwise they will most probably be disappointed in obtaining a copy. Purchasers of single copies are asked to deal through a bookseller or photographic depot.

The features of the ALMANAC are sufficiently well known, but attention may be specially directed to certain constituents of the forthcoming volume:—

1. *Contents*, serving as a guide to the pages, and showing at a glance in which portion a given item of information is to be sought.
2. *An Index* of nearly every individual fact, formula, and paragraph, serving to take the consultant to his subject at once.
3. *Photographic Copyright*. A popular exposition of the subject in its present-day applications.
4. *Epitome of Progress*, classified and codified. A review of the year's work in technical and scientific photography; in which everything on a given subject is assembled at one place in the volume.
5. *Contributed Articles* by leading writers.
6. *A Frontispiece*, in Barnet Platino-Matt bromide paper, of Miss Billie Burke.

The Tables, Formulæ, and other features of the volume have been revised and re-arranged, and, it is hoped, will meet with the approval of every one of the 25,000 prospective readers of the 1906 ALMANAC, which in mere size, the publishers must confess, is greater than any of its forty-four predecessors.

lamp and compensate for the expenditure on current. Where neither of the above suggestions is practicable, the method of adding a small proportion of potassium bichromate to the developing solution may be tried. It has given in our hands excellent results with negatives too soft in contrast and with slightly over-exposed prints, or prints which have absorbed a little moisture in printing. Thirty-five minims of a saturated solution of bichromate of potash are added to 10 ounces of the ordinary oxalate developing bath. The effect is not so much to lighten the print, for the shadows appear scarcely affected in depth, but to increase the contrast, lightening the half-tones and lighter tints and clearing up the whites. Muddiness is entirely removed. We have not been able to secure such marked results with sepia paper as with the black.

A Seasonable Precaution. The exceptionally cold weather for this time of year which we have had in most parts of the country during the last week has been sufficient to set the "weather-wise" predicting that we shall have a long and severe winter. Weather prophets for the past few years, when a spell of low temperature has set in towards the end of November, have predicted the same thing, but, alas! for the prophets, their predictions have not been fulfilled. It is several years now since we had what some are pleased to call "a good, old-fashioned winter." A season of that description is all very well in its way, but it is not altogether an unmixed blessing, more particularly when, as was the case with many a few years ago, it is accompanied by a frozen water supply that may last for weeks. Frozen pipes may usually be avoided if timely precautions are taken, and the trouble involved is so slight that even if it is found that they were not necessary the time can scarcely be considered as wasted.

Frozen Water Pipes.

Here are a few practical hints that may be useful. In the first instance the supply from the street main should be considered. If the pipe is laid deeply in the ground there is little likelihood of its becoming frozen, but it will be well to protect the main cock by stuffing the access to it with some old felt carpeting. Should it, however, be laid near the surface it may require some protection in the case of a hard frost, and a good one is some five or six inches of old stable manure well trodden down. All outside pipes should at once receive protection. At most ironmongers' a thick felt is sold specially for the purpose. Two or three thicknesses of this, wound round, or nailed over, the pipes afford good protection, felt being an excellent non-conductor of heat. Failing felt, some hay-bands, obtainable at the corn-chandler's, answer nearly as well. If the water is supplied to a cistern, the latter should be seen to. If out of doors it should be well covered up with old carpet or straw, or both. If indoors, it will, except in a few cases, require no consideration, the heat of the building being usually sufficient to prevent the water from freezing; but the pipes from it, if they go to outbuildings, may require protection, and the felt just mentioned is the best for the purpose. It is a good plan during a hard frost to empty the pipes every night, and this may be done without wasting the water in the cistern. The neatest way of doing it is to have a stop-cock just below the cistern, with an air-cock a little below that. Then, if the stop-cock be closed, and the air-cock opened, the pipes will be emptied when the lowest taps are turned on. An extemporary arrangement which will serve the same end may be made as follows:—Get a

a.

piece of iron tube, known as gas barrel, long enough to reach a few inches above the water when the cistern is full, and a little less in outside diameter than the inside of the outlet pipe. Wind the end round with rag and plug it into the outlet pipe. Then if the lower taps be opened air will enter the tube and the water will drain out of the pipes. The iron tube can be removed in the morning and the service restored.

Burst Pipes.

If perchance a pipe becomes frozen, it should without delay be examined throughout its length to see if it has burst anywhere. The burst will be seen by a bulge in the metal at that part, and, if one is discovered, the services of a plumber should be sought at once, for while a frost lasts they are at a discount whereas when a thaw sets in they are at a premium, and often only to be had after long delay and after much damage has been done by the flooding of the place. If a plumber is not to be had, the pipes may be temporarily repaired in the following simple way. First carefully pull the pipe, for some length, away from the wall, and with a bradawl chip out the ice. Then with a couple of hammers, using one as an anvil, close the fissure as closely as possible. Next take a piece of stout calico large enough to go two or three times round the pipe and spread on it a plaster of ordinary white lead mixed with dry red lead. Bind this tightly round the fracture and over it bind a few strands of strong wide tape, and, finally, bind round with string. A repair thus made, if carefully done, will last for many months even on a high pressure service. If the burst is not detected until the thaw, and the place is being flooded with water and the flow cannot be immediately stopped, the best procedure will be to batter up the pipe with a hammer a few inches from the break. This will entail a little extra work for the plumber, but it may prevent a great deal of damage being done to the premises.

Cold Weather and Stained Negatives.

Cold weather is often productive of silver stains on negatives, in a way unsuspected by many photographers. During dark weather, the printing frames are frequently exposed out of doors, when they become exceedingly cold. They are then brought into a warm room to change the prints, and moisture immediately condenses upon them, often palpably in the form of dew on the glass side of the negative. When the frame is opened moisture also condenses on the film, and, if that is not varnished, is absorbed by it. With the repetition of this changing several times during the day a considerable amount of moisture becomes absorbed by the gelatine, with the frequent result that the film gets stained by the free nitrate of silver in the paper, more especially if that also contains, as it usually does, some moisture from the air. In this way negatives frequently become silver stained without the cause being suspected. The remedy is to have the negatives varnished or, failing that, to slightly warm them before the fire, so as to eliminate the moisture before fresh paper is put upon them.

The Free Portrait Swindle.

The notorious Tanqueray, it appears, has an imitator—of course in Paris—who is sending circulars all over this country offering to make enlargements free of any charge from any photograph. A correspondent sends us three of these circulars received by a friend of his, who sent a photograph. In the first this man, or firm, for it is B. and Co., offers to make absolutely free and without any engagement whatever

on the part of the addressee, an *artistic portrait* life-size. Owing probably to the exposures of the Tanqueray system this firm adds, with the greatest impudence, the following to their offer:—"Perhaps you have already received similar propositions from other houses, but could not get the portrait free unless you agreed to buy a frame. Now we ask nothing of the kind. *You are at perfect liberty to purchase your frame wherever you like.*" A portrait is sent; then in due course comes a second communication saying the enlargement is finished, and that "it is a real masterpiece, and the resemblance is perfect." With it is an illustrated catalogue of frames suitable for this masterpiece, varying in price from one pound four shillings to two pounds eight shillings. This letter winds up with the request that if a frame is not required a postal order for eight shillings be sent to cover the forwarding expenses of "your magnificent portrait." Next comes a third letter reminding the sender of the portrait that the firm are still waiting for his instructions, and asking for the eight shillings to defray the forwarding expenses. The same old Tanqueray dodge. If the money is not sent, of course, the original is not returned.

Free Portrait Swindles In London. We suppose that so long as the British public can be gulled by being promised something for nothing, these Paris concerns will flourish. But these swindles are not confined to Paris alone; they are being practised here to a large extent. Last week a couple of young servant girls complained to the magistrate at the Westminster Police Court that their portraits had been obtained from them by a canvasser who promised to do enlargements of them gratuitously to advertise a new branch business to be opened in the locality. Proof enlargements were submitted, and extortionate demands made for frames, which had not before been mentioned. As the girls refused to have the frames, the return of the original portraits was refused, hence the application to the police court. The magistrate ordered the police to make inquiry into this class of business, and said that if the pictures were not promptly returned summonses would be issued. No doubt they have been returned long before this. Often the portrait sent for the free enlargement is of some departed relative, perhaps the only one in existence, and to get it back its owner is frequently coerced into paying an exorbitant sum for a frame. Or, as transpired at the police court, young girls are often frightened into making the payment. It is to be hoped that the police will be able to put a stop to this kind of business, in this country, if only for the credit of photography.

ARTIFICIAL LIGHT IN THE STUDIO.

SOME years ago we were looking over the premises of a provincial photographer, recently opened, elaborately fitted, and controlled by a man who thoroughly knew his business. There was an installation of electric light which we were told had cost a hundred pounds, and the photographer surmised it would be a hundred years before he got his money back. Since then our friend has probably changed his opinion, for artificial light is now regarded not as a luxury but as a necessity in all but the smallest of towns, and of all forms of lighting the electric light is the most practical. From the Cooper Hewitt mercury vapour lamp we expect great things in the future. In many respects it is the ideal illuminant, soft, steady, uniform, silent, and easy to install. Its one defect, the peculiar colour which flesh and other objects have under its rays, would appear to be comparatively easy of removal if it were attempted in a scientific way.

It is not our intention to speculate, however. We wish to point out some of the principal defects of work done by means of artificial light, and to suggest methods for their avoidance. It is almost universally admitted that good daylight is unsurpassed as an illuminant for portraiture, and if we can briefly ascertain what are the best characteristics of daylight and endeavour to modify our artificial light so as to imitate these characteristics we shall maintain a desirable uniformity in the output of work. In daylight work we have a comparatively large illuminating area, and the light entering, although termed a "direct light" so far as the sitter is concerned, is in a state of diffusion, being reflected by clouds, moisture, and dust particles in the air, and the countless objects within sight of the studio windows. This light, by means of opaque and translucent blinds, we control as to its quantity, quality, and direction. In the use of artificial light we have both a much less volume of light and a smaller illuminating area. The natural tendency, therefore, in using such an illuminant is to produce results with harsh contrasts, and not only are the actual contrasts too great for proper registration on the dry plate, but they are emphasised by close proximity, the result being lack of half-tone. In too many cases the unskilled use of reflectors to soften the heavy shadows only leads to cross-lighting with its falsification of the modelling and its frequent destruction of the true expression of the eyes. Starting with what is more or less a point of light, the maker of the lamp increases the illuminating area as much as possible, in some cases by the use of a reflecting surface behind the light and a small disc to cut off all direct rays, and in other cases by the reflecting surface and a diffusing medium instead of the opaque disc. It will be at once apparent that the illuminating area will be larger, relatively to the head, the nearer it is brought to the head, and this is one of the most important points in using any form of light mounted in a parabolic reflector. In parenthesis, we may suggest lighting all heads with the lamp at one or other of two distances, the nearer for soft lightings, and the other a little more distant for more vigorous work, and in order that exposures may be regulated with fair accuracy the two distances should always be adhered to, so that the light reaching the sitter is kept uniform.

Turning to the softening of contrasts and production of half-tones, we have two courses open to us. We may further diffuse the light, using a large diffusing screen of tracing linen or similar material, and so obtain a larger illuminating area, but a weaker light. This method will not increase the exposure, because the shadows will be no darker, and we should have had to expose for them previously. It will considerably lower the tone of the high-lights, and the light will play round into the shadows forming half-tones. One decided objection to this method lies in the lowering of the high-lights to such an extent that brilliance is often lost and the retoucher must be relied on to replace the tipped high-lights.

The alternative method consists in the greater use of reflected light. In daylight work the studio walls form reflecting screens, and owing to the considerable area of light-admitting space the reflected light is also of large area, and the shadows are prevented from becoming heavy and solid, while no distinct effect of cross-lighting is present. But with artificial light the walls, even if light in colour, are insufficient, first, because only a small part of them is illuminated, and, second, because as a rule they are so far away that the light reflected becomes very weak before it reaches the shadow side of the head. A reflecting screen of light grey and of large size is needed, so placed as to catch all the light from the

lamp which passes in front of the sitter and throws it back on to the portion of the head where shadow and light meet. In this way cross-lighting is avoided, the reflected light continuing the direct light and leaving some touches of shadow on that side of the head furthest from the principal light. By a careful use of a large reflecting screen

it is possible to raise the tone of the shadows, lessening the contrast, and thus the operator is enabled to shorten the exposure. The stronger light gives more force to the modelling and usually a better lighting of the hair which is an important matter in the case of ladies' portraits.

A RAPID AND CHEAP MIXED DEVELOPER.

SOME time ago I thought that a combination of pyrogallie acid and hydroquinone should produce a good non-staining developer, giving a much more non-actinic coloured image, than an ordinary hydroquinone formula, and at the same time quicker in action. I therefore tried a combination of the two developing agents, and the result proved my idea to be correct. And it produced a much more rapid developer than I anticipated—i.e., much more rapid than the usual hydroquinone and carbonate of soda, or carbonate of potash, developer, as the image began to appear in from forty to sixty seconds, and full detail and density were obtained in from ten to twenty minutes. I believe that a factor of from 10 to 16 would be suitable if Mr. Watkins's system of timing development is adopted; a factor of 10 to 12 for portrait and group negatives taken in the autumn and winter if intended for printing out on P.O.P.; and a factor of 14 to 16 for negatives taken in the spring and summer, will probably be suitable. As the colour of the image is very non-actinic, negatives will produce much better prints than their visual appearance would indicate, being very similar in tint to those developed with the pyro-ammonia developer when very little sulphite of soda is present in the developer.

Stock Solutions.

No. 1.—Distilled or boiled rain water	5 ounces.
Anhydrous sulphite of soda	2 drachms.
Citric acid	about 10 grains.
Pyrogallie acid (heavy crystals)...	30 to 60 grains.
Hydroquinone	60 grains.
No. 2.—Distilled or boiled rain water	20 ounces.
Anhydrous sulphite of soda	2 ounces.
Anhydrous carbonate of soda	2 ounces.
Bromide of potassium	20 to 40 grains.
Formalin (10 per cent. sol.)	20 to 40 minims.

NOTES.—Re No. 1 solution: If preferred 15 to 20 grains of metabisulphite of potash can be used as a preservative instead of sulphite of soda, and the citric acid; only enough of the latter to render the solution slightly acid to blue test paper is necessary. If too much contrast is produced owing to the colour of the image being too deep in tint, only use 30 or 40 grains of pyro, instead of 60 grains, in future, the proportion of the hydroquinone remaining the same as stated. Or the development factor can be reduced if desired instead.

Re No. 2. Solution. — No bromide of potassium or other restrainer will be required with some brands and speeds of plates or films, but, as a rule, except perhaps for very rapid exposures with the focal-plane shutter, I think that a little bromide of potassium in the developer is a decided advantage, as it tends to produce a non-actinic coloured image and prevents chemical fog. But in cases of over-exposure more bromide or other restrainer must be added to the developer.

No. 3.—Bromide of potassium (or chloride of sodium, or citric acid)	1 ounce.
Distilled water	to make 10 ounces.

The bromide of potassium tends to produce a yellowish coloured image, and the chloride of sodium and citric acid gives images grey or black in tint. The restraining power of the chloride of sodium is slightly greater than that of bromide,

and the restraining power of citric acid, citrate of soda, or citrate of potash, exceeds that of either bromide or chloride of sodium.

So when either of the restrainers mentioned are used instead of bromide of potassium, it may, and probably will be, necessary to carry the development a little farther than when the former is employed, owing to the image being less non-actinic in colour. The addition of a small quantity of formalin 10 per cent. solution to the No. 2 stock solution is to prevent the gelatine film from softening, melting, blistering, or frilling. It may also act as a slight accelerator to the developer, when sulphite of soda is the preservative used in No. 1 stock solution, but it will not act in this way if metabisulphite of potash is used instead. When the temperature of the dark room and of the developer is much higher than 70 deg. F., the presence of formalin in the developer is a necessity. When it is 70 deg. F., or below this temperature, it is advisable, and I recommend it, because the films can be washed safer, dry much quicker, and are less likely to be damaged by insects, while drying.

Developer.

Stock Solution, No. 1	1 to 4 drachms.
Stock Solution, No. 2	2 to 8 drachms.
Water	to make 4 ounces.

The No. 1 solution gives density, and the No. 2 solution produces detail, and increases the speed of the development.

The following I consider a normal developer:

Normal Developer.

Stock Solution, No. 1	2 drachms.
Stock Solution, No. 2	2 to 4 drachms.
Water	to make 4 ounces.

It is usually advisable to start the development with one or two drachms of No. 2 sol. (in case the plate or film should be over-exposed), and to add more of the latter if required. When the exposure is correct the image begins to appear in 40 to 60 seconds, and the detail and density are complete in from 10 to 20 minutes. As a rule I use as small a quantity of No. 2 sol. as possible, i.e., only enough being added to produce all the shadow detail required; the negative is then allowed to remain in the developer until it is dense enough. By working in this way excessive density is easily avoided, and the danger of fog, etc., is greatly reduced. Keep the dish covered, and in motion while development is proceeding, in order to avoid uneven development, stains, and fog. Well wash the negative before fixing or the film may be stained yellow, and the time taken to print lengthened more or less in consequence. Each 4 oz. of the developer will develop from two to four half-plates in succession, but it tends to stain the film a little, if not used up within about 24 hours, although it can be used about six days after mixing, and still produce good negatives; but I prefer to use the developer only once or twice in succession, as then the film will not be stained at all. The following fixing solution works well:—

Fixing Solution.

Water	20 ounces.
Hyposulphite of soda	4 ounces.
Dry chloride of sodium	4 ounces.

The later tends to harden the film. All valuable negatives should be fixed for at least 15 minutes in two fixing baths

similar to the above, well wash the negatives after each fixing. In the event of obtaining negatives that are over developed, or badly stained, refix in a good acid fixing bath, which will remove some of (if not all) the stain, and render the colour of the negative more actinic than it was before, which will shorten the time required for printing. A suitable acid fixing bath is Mr. Edwards's, viz. :—

Water	20 ounces.
Hyposulphite of soda	4 ounces.
Metabisulphite of soda	$\frac{1}{2}$ to 1 ounce.

If the most transparent parts of the film are tinted or stained too much, the sulphite of soda in No. 1 solution can be increased to 3 drachms, or more if required. But care must be

taken not to use too much sulphite of soda, or the non-actinic colour of the image will be converted into a more actinic one, such as grey or black, which will render a longer development necessary, in order to avoid flat negatives.

All valuable negatives must be protected from actinic light while they are being washed after development, also when fixing, and while being washed after fixing. They will then be in the best possible condition for intensifying (should that be necessary) successfully with silver, or by any other method desired.

J. T. HACKETT.

[Probably exception will be taken by some readers, as it is by ourselves, to some of the claims made by our contributor.—Eds. B.J.P.]

PHOTOGRAPHY THE SERVANT OF SCIENCE.

[The Eighth Traill Taylor Lecture, delivered at the New Gallery, Regent Street, Oct. 24, 1905, by Chapman Jones, F.C.S., F.I.C.]

MR. TRAILL TAYLOR was a man of wide and deep sympathy. I once called upon him at his editorial office without notice, to ask him for information, probably in connection with some historical detail, and although I quite forgot the subject of the inquiry and the result of it, I shall never forget the readiness with which he left the work he was engaged upon and consulted volume after volume from his book-shelves to find what I wanted. And I believe that those who knew him best will agree with me when I say that the cordial sympathy that so impressed me on that occasion was natural to him.

But although one may take a wide interest in a subject and its applications, probably every worker has a preference for one section of it, and if I understood Traill Taylor aright he had a distinct leaning towards the use of photography for definitely useful or scientific purposes, rather than picture making or snap-shooting by purely empirical methods, or the consideration of the theories of photographic processes. I think he appreciated the abstract science of photography and the mere empirical applications of it whether in artistic work or for simple amusement, not so much as the methods of its intelligent use as the recording art. I venture therefore this evening to treat of a few details of photographic procedure in something of the way that I think he would have preferred.

Serious Photography.

The kind of photography that I have in view is such as the engineer, the geologist, the student of architecture, the spectroscopist, the microscopist, and many others practise, or ought to practise, when they seek to secure as perfect representations as possible of things or phenomena. We must presume a certain amount of ability and a desire to perfect one's methods, rather than the careless attitude that is all too common even in scientific workers, many of whom seem to regard photography as nothing more than the following of the instructions on the packets of the sensitive materials employed. It is obviously impossible to deal with the whole subject at the present time, but I hope to treat of a few matters of fundamental importance, though I fear in all too superficial a manner.

Truthful Definition.

First with regard to the lens. During the last dozen years or so, innumerable methods have been proposed for getting at the properties and capabilities of lenses, but very few of these are suitable for the individual I have referred to. It is out of the question for him to purchase costly apparatus for the purpose, to set up elaborate arrangements, or to adopt any method that requires special skill or prolonged practice to obtain reliable results. He does not care to know why a lens will or will not serve his purpose, he has no wish to discriminate between the various aberrations, but he does want to know what a lens

will do, and sometimes wherein and to what extent one lens differs from another in its performance. The matters that concern him immediately are: (1) truth of outline in the image; (2) covering power, or extent of the image; (3) fineness of definition; (4) depth of definition; (5) absence of false images and lights. According to circumstances one or more of these may be of no importance; for geological and architectural work, for example, fineness of definition is negligible, for any lens intended for serious work will define sufficiently well.

A Test for Distortion.

Concerning truth of outline, that is, the absence of distortion in the image. This is commonly tested for by seeing if a straight line in the object is straight in the image, a test suggested by the most obvious result of the error, and which has also given rise to the name of "rectilinear" for lenses that are free or comparatively free from it. This method is troublesome in practice, for lines that are supposed to be straight are often much otherwise, and those that might serve are not always in convenient positions. Moreover, at best, curvilinear distortion is only a secondary effect, and its reason is not always understood, for I have known even an optical expert to think that a diagonal line was a better test than one parallel to the side of the plate, because it was longer. The error is due to a variation of scale along any radius drawn from the centre of the lens field, and this variation can be measured directly by photographing an equally divided line, or lath, or scale, so placed that its image crosses the centre of the field, and then examining the resulting image for equality of the spacings in the photograph. This method has not only the advantage that it deals with the error itself in a fundamental way, but it gives the definite magnitude of the error and shows at once how much of the field is free from it, in one experiment, neither of which the straight line test can do. It needs no special apparatus, and I think that it is more easy to carry out than the other.

The elimination of distortion in even the best of lenses is only comparatively successful. I can give a definite idea of its amount from some results of Dr. Kæmpfer's. A collinear of focal length 15 cm. and aperture $f/6.3$ at inclinations from 10 deg. to 37 deg. from the axis, gave deviations from a little over one-tenth to practically a whole mm. Such a lens is not useful for the most accurate photogrammetrical or astronomical work. To avoid these errors a special collinear was calculated in this instance, and this gave deviations from less than one-hundredth up to about a tenth of a mm. at similar angles. That is, the maximum displacement of the image within the angle stated was reduced from about the twenty-fifth of an inch to the two-hundredth of an inch. But it is still at least

four times as great as the defining or separating power of some good lenses as estimated by their performance on gelatine plates.

The Covering Power of Lenses.

The second property of the lens is its covering power, but this is so intimately connected with the work to be done, that is, the degree of perfection of definition required, that each worker will very probably prefer his own method of determining it. For general rather than specific purposes there is no better test object than a flat wall to which are attached designs of the kind now so well known. But if it is desired to determine the actual defining power of the lens, that is, its power to render minute detail, then a different method is to be preferred. I have found convenient three groups of three or four black lines, the lines and spaces being, in each group respectively a quarter, a half, and one mm. in breadth, the lines being drawn with Indian ink on white cardboard. There are also three holes, a half, one, and one and a half mm. in diameter respectively, opening into a comparatively large box lined with black velvet. There are five of these groups of lines and holes arranged in steps, so that the distance from the lens to each is 30 mm. less than to the next more distant one. The middle one is focussed on, but the others are necessary, as it is impossible to be sure that the object focussed on will be the sharpest when the exposed plate is developed. The want of flatness of the best plates is enough to make this precaution necessary. In making the test, the arrangement is generally just twenty times the focal length of the lens away, so that the images of the holes are from one to three-fortieths of a mm. (or one- to three-thousandths of an inch) in diameter, and the lines in the image are one-eighth, one-fortieth, and one-twentieth of a mm. (or the two-thousandth, one-thousandth, and the five-hundredth of an inch) in width. The arrangement described allows for a total difference between the image plane and the plate of one-seventh of a mm. (a little more than the two-hundredth of an inch) on each side of the plane, almost irrespective of the focal length of the lens.

Depth of Definition.

For the last half-generation or so we have been told in season and out of season, and with remarkable emphasis, that depth of definition depends absolutely and only on focal length and aperture, and that the old idea to the contrary was altogether wrong. I venture to say that while the old idea was confused, curvature of field taking part in it in an uncertain way, the new notion is in error, being an attempt to force theoretical conditions that can never be realised into the position of practical facts. In the middle of the field depth of definition does depend almost entirely upon focal length and aperture, though even here spherical aberration is not without effect, but a photograph is not made for the sake of a little patch in the middle of it. The characteristic necessity in a photographic lens is the power to define over a large field, and it is chiefly a practical recognition of this fact that has led to so much improvement in lenses during late years. At an angle of, say, 30 deg. from the axis the depth of definition may be almost at its maximum, as in the original double anastigmat of Goerz, while in the same part of the field another lens may show no depth at all. To suggest that the depth of definition is equal in two such cases as many would have us believe, is to my mind absurd. The measurement of the "focal volume," that is, the area of a diametrical section cut through the solid figure that would fill the whole space within which the defining power of the lens does not fall below the adopted standard, is a useful method of comparison, but better still is the diagrammatic representation of this section. Of course the practical depth of definition depends upon the standard of defining power adopted, and this will vary according to various needs.

A Test for Ghost Images.

All lenses give false light, that is, they transmit light that takes no part in the formation of the image, and I think I may say that this light is never evenly distributed over the plate. This must be borne in mind in measuring the densities of a negative for the purpose of finding the proportional luminosities of the object. But occasionally this false light is concentrated and gives, under trying circumstances, obvious "ghosts." I have seen the white shirt-front in a man's portrait repeated in the space above his head so obviously that the portrait was, even commercially, useless. Such a lens might give gross errors of density. A useful way of discovering such "ghosts" is to focus a bright flame, keep the focussing screen and eyes well protected from light, and slowly move the chief image of the flame a little away from the centre of the screen while looking on the other side of the centre for a false image. The lens should also be racked in and out to make any false image more conspicuous by focussing it, and as the primary image is brought into sharp definition any ghost that may be observed should enlarge, by being thrown out of focus, until it covers the whole, or nearly the whole, plate, and so become invisible.

If these points are looked to, or such of them as may be regarded essential, one will get a very good idea of the comparative advantages of lenses from a purely practical point of view. I have said nothing about working to focus. I have met with some lenses other than very cheap ones that failed in this respect, but such failure is doubtless exceptional. Moreover, this matter is very uncertain now that the colour sensitiveness of plates varies and coloured screens are so commonly used. With regard to lenses that are worth being called lenses at all from the point of view that we have assumed, the character of the colour correction is a special matter that must be examined if necessary by special means according to the work that is to be done. With some even excellent lenses it is necessary to focus with the coloured screen in position, as by inserting the screen afterwards the definition is very much degraded.

Cameras, Ancient and Modern.

As to cameras there is little to say, but that little is of first importance. The function of the camera is to hold the lens and the sensitive surface in a definite relationship to each other—the lens axis should be perpendicular to the sensitive surface and cut it at its centre unless shifted from this position for a definite reason. Comparatively few modern cameras do this. They hold the lens and the plate, but the relationship between the two is often an unknown quantity, and I do not know of any ready means of determining it. The old type of fixed front camera with a single base-board supported by a wing such as Meagher made, erred less in this matter than the modern instrument with a small folding front and telescopic base-board. And it is doubly unfortunate that the deterioration of cameras in this respect is almost contemporaneous with the improvements in lenses, for the finer the lens the more carefully must it be mounted to take full advantage of its quality.

I suppose that there will be few, if any, objections taken to what I have said so far, but this I am afraid will not be the case with what remains to be said. Whether this is so or not, I propose to continue to give the results of my own observations and investigations. My advice must be accepted for what it is worth—I act upon it myself.

The Speed of Plates

We have had lately a great deal of hair-splitting about the sensitiveness of plates. Taking the general sensitiveness, I doubt if there is one case in a hundred—if one in a thousand—where an increase of less than 50 per cent. is noteworthy. For example, the cases where a plate marked 300 Hurter and Driffield would be appreciably better than one marked 200 Hurter and Driffield solely on account of its greater sensitive-

ness as so measured, must be very rare. Such an increase may be of great use to the maker, as it may show the way to get another 50 per cent. rise, and a doubled general sensitiveness is of value to the photographer, though not always so much as he fancies it is. And, after all, what is general sensitiveness? It conveys about as much information regarding a plate as a statement of the number of books it contains does with regard to a library, and of what help would it be to a literary man to tell him that this library contains fifty thousand and that other seventy thousand volumes? I have a great regard for Dr. Hurter and Mr. Driffeld, and recognise the importance of the work they did, but I think it was very unfortunate that the bulk of it had for its aim the getting of an exact method of estimating general sensitiveness, a thing which in the nature of things is impossible.

The comparative uselessness or insufficiency of estimations of general sensitiveness is not a mere matter of theory. I have found "ordinary" plates more sensitive to red than plates boasting of red sensitiveness, and slow isochromatic plates more sensitive to green than isochromatic plates "specially rapid," "snap-shot," or whatever else may happen to indicate great sensitiveness.

But of course under *definite conditions* every plate has a definite sensitiveness, though not practically definite to so minute a degree as many seem to imagine. If the ordinary numerals are taken to indicate a sensitiveness scale, it is convenient if each alternate figure indicates a double sensitiveness. The old scale of Warnerke, in which each third figure indicated a double sensitiveness, was often for practical purposes inclined to be too minutely divided, still it seems not impossible that a scale in which every fourth figure means a doubled sensitiveness might be useful on special occasions, but this appears to be about the limit of the useful, if not indeed the possible, division of the scale.

The consideration of sensitiveness scales has a direct application in scientific work. In many cases a single exposure is quite insufficient for the getting of a satisfactory record, especially perhaps in spectrum work, often in photomicrography, as well as in other cases. I believe that not infrequently a great deal is lost because of the too prevalent idea among scientific workers that in photographing any given view of an object one photograph ought to suffice, and that to show several would amount to a profession of incompetency. This is quite erroneous, and I would here emphasise very strongly the desirability of making a series of photographs in all cases where the range of luminosities is great, that each part in turn may be rendered under the best conditions. But even if a single photograph can show every detail, and show it well, it is often impossible for the most skilful to judge as to what the best exposure will be, and the temptation is great to accept the first negative obtained if it seems good enough. Whenever it is necessary to make a series of photographs in order either to properly show the object or to select the best representation of it, I find as a rule that each exposure is advantageously double the next shorter. Less than this gives a difference rarely worth having, though for sensitometric purposes it is desirable to go a stage further and halve, or perhaps in some cases quarter, such degrees of exposure, as I have already stated.

Tests of Colour-sensitiveness.

The only perfect estimation of sensitiveness would be expressed as a spectrum curve, but for practical purposes it is not only sufficient but preferable to divide the spectrum into definite parts and estimate the sensitiveness to each. The division into two parts, as Dr. Eder has done, is not sufficient, as it ignores the differences between sensitiveness to red and green. The division into four parts, as in my plate-tester, is

I think, the most suitable for present-day requirements, that is, (1) all the light that ordinary plates are notably affected by, (2) green, or the added sensitiveness of the common type of isochromatic plates, (3) red, and (4) the red less refrangible than C. The sensitiveness of plates cannot be expressed by a single figure or single ratio except in a very incomplete and often useless way. As to the methods of estimating sensitiveness to various colours, I will only say that, for the practical worker, the refinements that some go to, even if possible, would be of no use. The simultaneous exposure through the four coloured screens and a neutral scale, the latter serving to indicate the value of the results obtained through the coloured screens, is not only simple and rapid, but gives results that, I believe, are quite sufficient for all practical work. If I wanted more perfect results I should still use the same method, but seek to perfect the compound screen that is now well known as the essential part of the "plate-tester." Much more might be said on this subject and plate-testing in general, but as I am now referring to only the most important matters in connection with the photographic work of scientific investigators, and indeed only to those of the most important matters that are too often misunderstood or neglected, I will pass on to the making of negatives.

The only function of the negative is to graduate the light that passes through it. Therefore a twofold truth must be aimed at in its preparation, namely, truth of outline and truth of opacity.* To this, for practical purposes, must be added unchangeableness, for what is the use of a record that is true to-day and false to-morrow? Truth of outline I have already discussed, and it will be convenient to consider the permanency of the negative next, for it may be taken as axiomatic that a want of permanency is a want of truth.

Development of the Plate.

A permanent negative must be a clean negative. Such a negative as, developed and fixed, should, as I have said before, consist of nothing but pure silver in clean gelatine. The firmly rooted and extensive aversion to purity in this matter would be curious if we could not account for it. It is claimed for unclean negatives that they have a delightful appearance and that they give better prints. With the first we have little to do, and the second I am prepared to admit if we regard the word "better" in the sense in which it is used. But should we judge of the value of documentary evidence by the fineness of the writing in which it is set forth? Should we say it is nicely written, therefore it is true? Should we in this matter prefer an ornamental lie to a plain truth? If not, why should we in photography? A photograph is a record, and the first desideratum in a record is truth, and to this everything should be subservient. An unclean negative gives a better print because the image is strengthened with the refuse matter resulting from the deterioration of the developer when the silver image is too feeble alone. This is the case either when the plates are so poorly coated that there is not enough silver to give a good image, or, if there is plenty of silver in the plate, when either the exposure or the development has been too short. It will surely be admitted that the best way to meet an error is to eliminate it, and that it is not best to seek to neutralise it with a second error. I have been asked why it should be considered a fault to have such a compound image. The answer is—Because the staining matter that results from the oxidised developer is uncertain in every way. Its deposition is accidental and its amount is uncontrollable; being soluble in the liquids used in the treatment of the plate, it will not be deposited proportionately to the silver; being coloured, its effect will vary with different lights and the varying sensitiveness of different printing materials, and its colour is liable to change and the plate can hardly be put into plain water or any solution without affecting it. Therefore it is difficult to conceive a

* I prefer to speak of opacity rather than transparency, because in a negative the transparency pre-exists and it is the opacity that is produced by the photographer.

worse material for the purpose of getting an image. To avoid it, use sufficient sulphite in the developer and fix after a mere rinse in hypo that contains both sulphite and alkali. The coloured matter is soluble in alkalis, but rendered insoluble, though lighter in colour, by acids; therefore avoid acid baths of all kinds, whether fixing baths or clearing baths, for the object should be to prevent its deposition and to maintain such conditions as will remove the little that may perhaps be deposited rather than to merely make it less visible.

I have very little to say about development. Many take a great deal of trouble about it and gain nothing thereby. For very much of the work that we are now considering, a single solution may be prepared that will keep in perfect condition for a year or so, and only need dilution for use. For myself I use metol and store it in four-ounce bottles with india-rubber stoppers. I am convinced that the simple time-method, that

is, allowing the plate to remain in the developing solution for a fixed predetermined time, modified a little when the temperature varies much, would often be found more advantageous than the anxiously careful method that we are all so familiar with. This will especially apply to work that involves the making of a considerable series of negatives under similar conditions. Of course variations in the image can be made by varying the development, but very few make them, even, I believe, of those who think they do. It is quite certain that absurdly extravagant ideas used to be held by some who ought to have known better, as to the character and extent of the possibilities of control in development, and the tendency to fly to the opposite extreme is the natural reaction.

CHAPMAN JONES.

[The remainder of the lecture will appear next week.—Eds. B.J.P.]

THE WEEK IN HISTORY.

Egloffstein's Half-tone Screen.

THE history of photography and photographic emulsion making, despite all its obscurities, is as crystal in comparison with our knowledge of the early efforts in photo-mechanical processes. Niepce and Talbot we know all about, it is true, but we plunge into profound gloom when we try to worm out the story of the modern half-tone process, and particularly of the half-tone screen. The early experimenters kept their results jealously guarded, but I believe Mr. Bolas and other students will bear me out in the assertion that the first published matter to describe the half-tone screen is Egloffstein's patent of 1865 (No. 3,053). It is entitled "Obtaining Printing Surfaces by Photography," and is curiously worded to refer to "the use of a heliographic and photographic spectrum," which "may

be composed of a single sheet of highly polished level ground glass plate, free from colours, and covered with a good asphaltum etching ground, heated and smoked over a wax paper in the manner of the engravers' black etching ground. The plate when cooled off is ruled over by the diamond or other point of a correct ruling machine, using light pressure to prevent the chipping-off of the ground and the flaking or breaking of the glass. . . . The plate prepared to receive the engraving is coated first with a sensitive heliographic varnish. Upon this varnish the spectral image is produced by the light falling through the open spaces of the spectrum. The spectrum is thus imprinted upon the varnish previous to its receiving the photographic image by means of a second exposure to the light. Both images are thus blended into one, the spectrum giving the texture to the photographic image." HISTORICUS.

DIFFRACTION GRATING REPLICAS.*

IN the early part of 1901 the writer entered upon a series of experiments having for their object the duplication of the plane grating, with the idea of producing a method which would yield definitely reliable results under conditions which might be easily satisfied. As these experiments have continued at intervals since then up to the present time, and have resulted in the manufacture of replica gratings of high grade, which are being widely used, it seems advantageous that a description of the method employed in their manufacture should be placed on record for the guidance of those interested.

The publication of these details has been purposely delayed in order that sufficient time should elapse to preclude the possibility of deterioration; and also that opportunity might be afforded for the collection of data relative to their behaviour. As both of those points have been answered in a satisfactory manner, there is therefore no further reason for delay.

The superior suitability of a transparent grating for a very considerable amount of work is, of course, evident, while the ease and certainty of production renders it possible that gratings need not be (as at present) excluded from high schools and kindred institutions on account of their cost. Apparatus may be constructed, or experiments undertaken, which would not be deemed advisable if one had to risk an original grating, while the duplication of gratings giving abnormal spectra is rendered not only possible, but easy.

It seems unnecessary that we should here enter upon a résumé of the various endeavours which have been made by earlier workers

in this direction, beginning with Strutt in 1872 and continued by him as Lord Rayleigh in 1896 and down to the present time. However, there is one name which should not be lightly passed by in this consideration, for Thorp, of Manchester, England, was the first worker to produce a really presentable grating-duplicate of considerable efficiency, and there is certainly owing to this worker from the scientific world a decided debt of gratitude.

The Ives Replica.

Mention may also be made of still another effort which is subsequent to that of the author. Mr. F. E. Ives, of New York, after receiving a few replicas from the writer became interested in the subject, and himself undertook the problem of making a successful replica. After a series of experiments, he succeeded in producing a cast which differed only in respect to its method of mounting. Owing to the fact that application has been made for patent,† complete details of the process are not available, but it is sufficient to state that claim is made for a replica in "a harder and less elastic material than celluloid," and with a similar contraction coefficient. This is pressed face down in contact with a piece of selected plate glass, and then covered by and cemented to another similar plate with a cement whose refractive index is the same as that of the cast. The writer was honoured by the receipt of one of these "new process replicas" upon their introduction about the beginning of the present year. When tested upon the spectrometer, it gave very good results—comparable with those manufactured by the method about

* We now reprint the full text of the paper referred to by Mr. Robert James Wallace in the note on "Orthochromatic Plates for Astronomical Work," published in our issue of October 27. The paper first appeared in the "Astrophysical Journal," and we are indebted to Mr. Wallace for a reprint of it from that publication.—Eds. B.J.P.

† Since publication of above the writer learns that no application for patent was made by Mr. Ives. The misstatement arises from the fact that the author was so informed by Mr. Ives's sales agent in Chicago.—R. J. W.

be described. Unfortunately, these casts do not seem to be permanent, as the cementing medium appears to be a solvent of the film, so that now diffraction colours are only to be seen in isolated patches.

Casts by Thorp's Method.

Thorp's method* consisted in flowing the original grating with a thin film of high-grade oil, upon which was poured celluloid in solution. When dry, this was peeled from the previously oiled surface and mounted face up on a plate of glass by means of a solution of gelatine and glycerine; the film being lowered gently and gradually into contact.

In all of the Thorp grating casts a very large number of air-bubbles are evident between the grating film and the glass support, the presence of which serves to scatter the light and impair the brilliancy and definition of the spectrum. In the method of mounting employed by the writer these air-bubbles are entirely eliminated, the replicas presenting a clean and brilliant appearance.

When in 1901 the matter of casting from the Rowlands' grating was begun, the method employed was that indicated by Thorp, viz., celluloid. A solution was made of gun cotton in amyl acetate, and then camphor was added in sufficient quantity both with and without the addition of alcohol. Innumerable difficulties were encountered, which, when suppressed or surmounted, simply gave place to others; and although considerable experimental work was performed, it but served to show the unreliability of this solution. These difficulties lay mostly in the direction of uneven shrinkage and opalescence of the film; while gratings of quality sufficiently good to define well in the spectroscopes constituted only about 20 per cent of the entire number.

A Modified Method.

In 1902 the results of further experiment led to the discontinuance of the preliminary coating with oil, and the exclusion of camphor in the solution. This change (together with an alteration in the method of stripping and mounting) resulted in much greater success in the production of replicas of a high grade, giving also a decidedly more brilliant film. This solution (which has since been in use without change) is composed of—

Amyl acetate, pure (Mallinckrodt)	64 ccs. (2½ oz.)
Anthony's snowy cotton	2.5 grammes (38 grains)

The cotton should be added to the amyl acetate in small quantities at a time, and well shaken until dissolved, after which it is allowed to stand during twenty-four hours. At the end of that time the resultant collodion is precipitated by being poured in a very thin stream into a large tray filled with water. The collodion should be poured from a height of at least three or four feet, and the water meanwhile should be constantly stirred with a glass rod. The precipitation does not immediately occur, the collodion collecting in an oily scum upon the surface of the water, which must be stirred from time to time during the course of the ensuing twenty-four hours.

When precipitation is complete, it will present the appearance of white or very light grey flocculent masses, which float upon the surface of the water, and are collected upon a clean filter paper and set aside to dry.

When thoroughly dry, it is again dissolved in the following proportions:—

Amyl-acetate, pure (Mallinckrodt)	64 ccs. (2½ oz.)
Precipitated cotton	2.5 grammes (38 grains)

and the collodion carefully filtered through paper—a process which may be advantageously hastened by the use of an aspirator or other form of air-pump.

The writer has prepared and used this collodion both with and without precipitation, but preference is given to the former as pro-

ducing a film which is not only more brilliant, but has a much more even and regular shrinkage in the stripping.

Making and Drying the Cast.

The grating to be duplicated is first carefully levelled in a roomy drying-cabinet, and, after dusting with a soft camel-hair brush, the necessary amount of solution is flowed over the face. The exact quantity lies within wide limits; too small an amount produces a film so thin that one has difficulty in handling it, while too much gives a film which dries with a more or less matt surface. By using always the same container one may drop the necessary quantity, and then, by inclining the grating, cause it to flow over the surface. From the container used by the writer twenty-five drops is the average amount for a two-inch grating.

It seems hardly needful to indicate that this flowing of the grating should be performed in an atmosphere as free from air currents as possible, thus minimising the danger of dust particles settling upon the surface during the operation. The grating is then placed upon the levelled support in the drying-cabinet, and the door carefully closed.

The drying is rather slow, a two-inch grating taking about eight to twelve hours, but it cannot be advantageously hurried. In the opinion of the writer, the slower the drying the better the result, as the solution gets time to fill perfectly the minute grooves made by the cutting diamond. It is a notable fact that casts made from collodions of different composition, and drying quicker, did in no case give results which were at all comparable with those which had been obtained by the slower method. It has also been noted that this film may be advantageously left in contact with the original for a considerable length of time, up to about three or four days, as it is much more easily handled in the process of stripping and mounting.

Mounting.

After an extended trial of various mounting mediums, which need not be enumerated, preference was given to a very thin layer of plain hard gelatine (with which the glass is previously coated and dried on a levelling-slab). The mounting is performed in the following manner:—

The gelatine-coated glass and the thoroughly dry grating are placed (face up) in a tray containing filtered distilled water at normal temperature, and the tray covered over with a clean glass. After a few minutes the extreme edges of the ruling will begin to show shadow bands caused by the contraction of the film, and thus pulling the lines "out of step." When this is observed the grating should be removed from the water, and any adhering globules shaken from its face; then, by a gentle pressure of the thumb nail at the edge of the clear portion of the polished circle, the film will be caused to spring apart from the original. This loosened portion is then grasped by the blades of a pair of wide "cover-glass" forceps, and with an even, slow motion raised from the original in a direction parallel to the length of the ruled line. Immediately the film is free it is laid face up upon the gelatine-coated plate (which is removed from the water for that purpose) in the same manner as in lowering a cover-glass upon a microscope slide; the plate is tilted to drain it of superfluous water, and the edge of the replica is clamped in contact, by means of a wide spring "letter clip" with notched edges. A piece of the softest velvet rubber, with a carefully cut edge, is now drawn very lightly and evenly over the replica in the same direction as in stripping, viz., parallel to the line length, and the plate set aside to dry.

This entire operation of stripping and mounting is very rapidly performed, and, although the description may appear lengthy in the recital, it can only be laid to the fault of the author.

It has also been found advantageous to "ring" the replica with

* Patented in England.

the casting solution after it has dried, and thus prevent the separation of the replica under extreme hygrometric conditions.

After-Shrinkage.

The contraction of the film during the process of mounting alters the number of lines to the inch, but such shrinkage is very small and is easily controlled within limits; viz., length of drying time. In those manufactured by the writer, which have a drying time of twenty-four hours, this contraction has been determined by careful measurement of over thirty replicas, with the following result:—

Width of original ruling, 28.867 mm.	} Mean of 10 settings each,
Width of replica ruling, 28.691 mm.	

which gives a difference of 0.176 mm. on the entire width of ruled surface.

The total number of lines on the original is 16,397; hence $568 = 1.0$ mm. On the replica the total number of lines divided by the width gives the new constant, viz., 572 nearly, or an increase of about six lines to each one thousand.

This contraction of the replica and the consequent increase in the number of lines to the mm. result in a greater dispersion of the spectrum. In a photograph of the region between λ 3933 and λ 4308 with the original ruling, the separation of the lines K and G was found to be 27.68 mm., as against 28.12 mm. on the negative taken through the replica.

Some Precautions.

The quality of the glass upon which the replica is mounted has much to do with its efficient performance in the spectroscope. It is not essential that one uses worked flats, but it is necessary that the surfaces be of fairly good quality; the glass in use by the writer is "white optical crown" which has been reground and polished, and which may be graded by preliminary observation in a spectroscope.

Not every sample of gun cotton will give an equally good film, for, under apparently identical conditions of manufacture, the results vary. This is undoubtedly due to the "personal equation" in the process of mounting, and for this reason they are tested and graded. Those of "second quality" are useful for projection purposes, and also in the chemical laboratory for the flame test of K, Na, etc.

Not every sample of gun cotton will give an equally good film, and from many varieties tested by the writer the brand before specified was with much care selected as the best—not only on account of the smoothness of the resultant film, but principally because it was found to be entirely free from any trace of acid. It will, of course, be evident that if this were not the case, it would only be a question of the number of casts made which would determine the life of the original grating.

Thorp's Test for the Quality of the Replicas.

If a replica grating be superposed face down upon the original ruling, and observed at an angle which equals that formed by the incident light, a series of more or less symmetrical shadow bands will be noted, which run approximately parallel with the ruling, and

LECTURE on "Copying" at the R.P.S.—In reference to our report of Mr. F. W. Brookman's lecture on "Copying," given in our issue for November 10, that gentleman has now written us amplifying our notice and correcting a slight inaccuracy. He says:—"The trend of experimental research in connection with the bathing of ordinary plates for colour sensitiveness has, of late, been more in the direction of their selective qualities for tri-colour work, and I am greatly indebted to Mr. A. J. Newton, of the L.C.C. School of Photo-Engraving, for his kindness in bathing a box of plates for me in pinachrome and pinacyanol. The latter dye, a sample of which he quite recently received from Prof. König, is admirably suited as a sensitiser for the blue printer, owing to its extreme sensitiveness to

are caused by interference on account of the slight difference in the line spacing. If the replica were absolutely perfect, the band would be straight, but in general they are slightly curved, such curvature forming (at the grating edge) an arc of a circle of radius approximately 1.5 metres. In but few cases have they come closer to a straight line than this, which may be considered as a fair average. The counting of these shadow bands was the method used by Thorp in determining the actual number of lines per inch in his casts—their number corresponding to the increase by contraction.

Absorption and Special Mounting.

On examination of these films in a quartz spectrograph, to determine their power of transmission for ultra-violet light, it was found that the absorption was practically nil up to λ 2613, and with slightly longer exposure they would transmit up to λ 2314. As glass practically stops everything beyond λ 3400, it has been suggested by Professor R. W. Wood (to whose kindness the writer is indebted for this examination) that they be mounted upon selected thin sheets of mica, which are even more transparent to light of shorter wave-length.

For special apparatus these casts may be readily mounted in a variety of ways suitable to the end in view, while for direct vision they may be mounted upon 30 deg. prisms of light crown. This method is very suitable in the construction of small spectroscopes, micro-spectroscopes, etc., and largely eliminates the possibility of poor definition due to multiple reflection from the faces of the glass plate when not accurately parallel.

The Effect on the Original Grating.

In conclusion, it may be remarked that the process appears to be absolutely devoid of any evil effect upon the original grating; in fact, the opposite is strictly the case, for concerning a one-inch grating owned by the writer, from which upwards of one thousand replicas have been taken, the surface appears to be as brilliant as when newly ruled. In cases where gratings have been in use in class instruction for a number of years, and consequently present a very bad appearance, being dull, surface-scratched, and greasy, the making of a number of successive casts restores in a great degree the original brilliancy. The explanation is obvious: the "dirt" on the grating is imbedded in the film while fluid, and, "setting" therein, is removed with the cast. A series of such casts from a dirty grating presents a good object-lesson as to the efficiency of this method of cleaning, being much superior to the means usually employed, viz., alcohol, ether, ammonia, etc. The replicas themselves are sufficiently tough to bear careful washing, their elasticity allowing them to be rubbed with cotton without injury.

Methods are now under consideration for giving a suitable reflecting surface to these casts, so that they may be produced either in the form of transmission or reflection gratings. Numerous experiments have also been tried in an attempt to duplicate the concave grating, but these, up to the present writing, have not given a sufficient measure of success to warrant their being recorded here.

ROBERT JAMES WALLACE.

red. I have made some quick tests for this lecture with and without a light yellow filter, with which latter the exposure was increased three times. Ilford H.T. plates were used for these experiments."

NORTH LONDON PHOTOGRAPHIC SOCIETY.—This society has been formed owing to the success of the recent photographic exhibition held at Highbury Vale. After the exhibition numerous letters were received by the secretary asking whether a photographic society could be formed in the neighbourhood; a meeting was called, and about forty attended. All North London photographers are invited to join, and may obtain a copy of the rules and any other information required from Mr. Charles Roberts, hon. sec. (pro tem.), 33, Riversdale Road, London, N.

THE "ZIGO" COMPETITION

For a paper which has been on the market only for the short space of some six months, the "Zigo" competition, organised by Messrs. Thomas Illingworth and Co., Limited, must be quite a record. An entry of seven thousand prints is something to boast of, but a still more praiseworthy feature of the competition is the very great variety of tones obtained on this simplest of self-toning papers. It appears the makers have been too modest in their claims for "Zigo." At any rate, they are giving the public an opportunity of judging for themselves of what the paper is capable by holding an exhibition of successful and other prints at Anderson's Hotel, Fleet Street, from Monday, December 5 to the 8th inclusive. The exhibition will be open from 11 a.m. to 9 p.m., and visitors will also have an opportunity of witnessing demonstrations of the process. The following is the list of prize-winners:—

Class A.—First prize (£5), M. E. Lomax, 87, Albion Street, Burnley; second prize (£2 10s.), John Webster, c/o Messrs. H. and C. Grayson, Limited, 179, Regent Road, Liverpool; third prize (£1), George Dunn, 8, Winney Street, Moston, Manchester; reserve, H. MacLennan, 339, Great Western Road, Aberdeen, N.B.

Class B. First prize (£5), G. Drury, Delmonte, Torquay; second prize (£2 10s.), J. V. Sublick, 17, Myddelton Square, E.C.; third prize (£1), F. G. Price, Aberbeeg, Monmouth; reserve, W. G. Llewellyn, 22, East Hill, Wandsworth, S.W.

Class C.—The following competitors have each been awarded a prize of £1:—J. Witcombe, 85, Holly Road, Maidstone; F. J. Taylor, 58, Stanley Road, Halifax; J. Clark, 34, Tennyson Avenue, Bridlington; W. B. Lamb, 39, Premier Street, Manchester; F. A. Forbes, 136, Clifton Park Avenue, Belfast; reserve, W. B. Westlake, 75, Chelverton Road, Putney, S.W.

Exhibitions.

SOUTHAMPTON.

The fifth annual exhibition of the Southampton Camera Club was opened on Tuesday last at the Philharmonic Hall, Southampton. The exhibition is again this year a great success, and reflects credit on the work of the energetic hon. secretary, Mr. S. G. Kimber, and the members of the club. No less than 553 entries are on view, including sixty-seven sets of lantern slides. The three southern societies (Southampton, Hove, and Southsea) have always been known for the strength of the lantern-slide entries, and this year is no exception. The open classes are extremely well supported, and include work by some of the best-known amateur photographers. The bulk of the work in these classes is being transferred *en bloc* to the Hove Exhibition and thence to Southsea, in competition for the special award offered jointly by the three societies. The judges at Southampton were Messrs. Frederick H. Evans and A. Horsley Hinton, and their awards were as follows:—

Open Classes.—Class A (any subject).—Plaque, "Surf," J. C. Warburg; plaque "A Dusty Day," Arthur Marshall, A.R.I.B.A.; plaque, "The River Thames from Tower Bridge," J. H. Anderson; plaque, "The Appeal," E. B. Vignoles and P. S. Greig, R.E.; plaque, "Sunset," W. A. I. Hensler; plaque, "Shoeing," H. W. Lane; plaque, "Strife," F. J. Mortimer; plaque, "Finishing the Plaque," C. B. Howdill, A.R.I.B.A.; plaque, "Tugging Home," W. Clayden; plaque, "The Life History of a Splash," A. C. Banfield; hon. mention, "Grey Morn," J. C. Batkin; hon. mention, "Staffordshire," E. B. Wain; hon. mention "The Last Leaves of Autumn," Dan Dunlop; hon. mention, "In the Evening Light," Rev. H. R. Campion; hon. mention, "Onora," Miss Marian Silverston; hon. mention, "Beyond," D. J. Scott; hon. mention, "Rue Damiette, Rouen," G. Bankart.

Lantern Slides.—Class B (any subject).—Plaque, "Gorse and Pines," W. A. I. Hensler; plaque, "The Summit," H. Wild; plaque, "Spring Sunshine," H. P. C. Harpur; plaque, "The Bend of the River," W. Mitchell; hon. mention, "Tintern Abbey," H. B. Smith; hon. mention, "Hops," E. Seymour; hon. mention, "In York Minster," E. R. Bull; hon. mention, "Queen Anne Half-Crown," Dr. T. H. Morton.

Postcards.—Plaque, "The Crypt Stairs," Rev. E. T. Clark; bronze medal, "White Currants," Robert Burnie.

Members' Classes.—Class C (Landscape, River Scenery, and Marine).—Plaque, "The Tree that Grew by Itself," W. R. Kay; plaque, "A November Morning," S. G. Kimber; hon. mention, "Grey November," H. Essex.

Class D (Portraiture and Figure Studies).—Plaque, "A Portrait of an Artist," W. R. Kay; hon. mention, "In the Library," George Vials.

Class E (Architecture).—Plaque, "Until the Day Breaks," S. G. Kimber; plaque, "Over the old Cathedral the Golden Sunbeams Fall," T. M. Weaver; plaque, "In Old Valais," W. R. Kay; hon. mention, "The Stairway, Christchurch," C. C. Cook; hon. mention, "The Sun's Bright Ray from Day to Day Falls on their Hallowed Resting Place," A. E. Henley; hon. mention, "Lead Kindly Light," S. G. Kimber.

Class F (Flowers, Animal, and Natural History Studies).—Plaque, "Whitehearts," A. E. Henley; plaque, "Miscellaneous Birds," C. M. Cooper; hon. mention, "Clematis," A. E. Henley; hon. mention, "Double Daffodils," A. E. Henley.

Class G (Lantern Slides, any subject).—Plaque, "Across the Valley," W. R. Kay; bronze medal, "Until the Day Breaks," S. G. Kimber; hon. mention, "Ambleside Mill," H. W. Miles.

Class H (Members who have never won an exhibition award).—Bronze medal, "The Baptistery, St. Marks, Venice," Dr. A. E. Bodington; bronze medal, "The Common," E. E. Rye; bronze medal, "Evening, Portsmouth Harbour," R. Robinson.

Gold Plaque for Best Average Exhibits.—S. G. Kimber.

Silver Medal, presented by the Editor of the "Amateur Photographer" for the best picture in the Members' Classes.—"Whitehearts," A. E. Henley.

Silver Medal, presented by the Editor of the "Photographic News," for the best set of slides in the Members' Classes.—"Waterfalls," H. W. Miles.

A good programme of evening entertainments has been arranged for the week, and yesterday evening (Thursday) the Mayor of Southampton (Henry Cawte) distributed the awards, which take the form of specially designed plaques. To-night an illustrated lecture on "Nelson's Battles" will be given by F. G. Ryder; and to-morrow evening illustrated lectures on "Antient Southampton," by G. T. Vivian, and "A Holiday in Switzerland," by W. R. Kay, will be given.

PLYMOUTH.

THOUGH there are a number of photographic societies in Devon and Cornwall, there are by no means so many exhibitions as might be supposed or expected. Plymouth is the commercial centre of the two western counties, and an admirable place for an exhibition intended to draw together the photographic workers of the district and those further afield. The present exhibition is the third of the series, and the entries show a satisfactory increase over those of previous years, reaching to nearly three hundred and fifty. But as some included several prints on a mount the actual number was in excess of this. No exhibition in the district has ever had so many classes provided for workers, and it is a moot point where the advantage comes in, except that it increases the opportunity of secur

ing awards. The judges have been liberal in their encouragement of merit. The adjudications were made by Mr. H. Snowden Ward, F.R.P.S., and Mr. H. S. Hill, M.J.I., a past-president of the Plymouth Photographic Society. The awards are as follows:—

Specials.—Gold Medal (Class K, No. 30), E. J. Jarvis. Photogram Plaque (Class C, No. 8), G. Bird. Best in Class D and E (Class D, No. 14), W. Clayden.

Class A (Architecture).—1 (26), S. G. Kimber, Highfield Southampton; 2 and 3 (12 and 13), W. A. Clark, Moseley, Birmingham; diploma of merit (8), E. G. Turney, 15, Leigham Terrace, Plymouth; diploma of merit (10), T. Bartlett, Perry Street, Aulaby Road, Hull; diploma of merit (16), H. Wormleighton, 8, Ashley Road, Leicester.

Class B (Animal Life).—1 (1), W. O. E. Mead-King, Courtfield, Hayn Hill, Maidenhead; 2 (9), W. Clayden, Millbay, Plymouth; 3 (22), A. Haynes, London Road, Alderly Edge; diploma (10), A. Durin, Wootton-under-Edge, Gloucester; diploma (15), F. Sloman, Sidwell Street, Exeter.

Class C (Child Life, and Children at Play).—1 (37), E. W. Hearn, 9, Sea View Avenue, Plymouth; 2 (6), W. Clayden, 8, Bounds Place, Plymouth; 3 (8), Graystone Bird, 38, Milsom Street, Bath, and (20), J. H. Wilson Collets, Wormingford, Colchester; special diplomas (18, 19), F. E. Weeks, 16, Lockyer Street, Plymouth; diploma (9), Graystone Bird, Bath; diploma (29), V. Thornton Paul, Morrab Studio, Penzance; diploma (21), A. W. Walburn, Upper Park Road, West Hartlepool; diploma (11), A. Debenham, 28, Union Street, Ryde, I.W.; diploma (15), Stanley Sowten, 1, Whitefield Terrace, Plymouth.

Class D (Devon and Cornwall Scenery).—1 (14), W. Clayden, Plymouth; 2 (20), E. Lees, Engelberg, Ilfracombe; 3 (31), E. J. Jarvis, 94, Treville Street, Plymouth; diploma (4), Fred Johnson, 24, Athenæum Street, Plymouth.

Class E (Landscapes).—1 (22), F. Judge, White Rock, Hastings; 2 (15), W. A. Clark, Moseley, Birmingham; 3 (25), J. Herbert, 52, Thornton Street, W. Hartlepool; diploma (24), M. Harding, 161, Union Street, Plymouth; diploma (2), Frederick Johnson, Plymouth.

Class F (Character and Costume Studies).—1 (8), W. H. Foxall, Grosvenor Avenue, Tunstall; 2 (11), J. Smith, 45, High Street, Hastings; 3 (6), W. Clayden, Plymouth; diploma (7), A. E. Coleman, 14, St. George's Terrace, Stonehouse; diploma (9), A. Debenham, 28, Union Street, Ryde, I.W.

Class G (Humorous Pictures). 1 (6), F. Sloman, Exeter; 2 (7), E. J. Jarvis, Plymouth

Class H (Streets and Street Scenes).—1 (11), A. W. Walburn, West Hartlepool; 2 (3), A. Brand, 42, Frankfort Street, Plymouth; 3 (13), V. T. Paull, Penzance; diploma (9), G. A. Towers, 120, Cambridge Street, Rugby; diploma (10), J. A. Wilson, Colchester.

Class K (Seas, Seashore Life, or Seascapes).—1 (30), E. J. Jarvis, Plymouth; 2 (27), V. F. Paul, Penzance; 3 (9), W. Clayden, Plymouth; diploma (26), T. H. Rolstone, 4, Market Place, Plymouth; diploma (31), A. F. Jewers, 41, Torrington Place, Plymouth.

Class L (Types of Beauty).—1 (8), H. T. Jessop, 15, Rolle Street, Exmouth; 2 (1), W. O. E. Meade-King, Maidenhead; 3 (10), F. A. Swaine, 6, Grove Road, S., Southsea; diploma (3), H. Morris, Queen Street, Newton Abbot.

Class M ("At Work")—1 (9), A. E. Colman, Stonehouse; 2 (11), H. W. Willcombe, Holland Road, Maidstone; 3 (4), A. Brand, Plymouth; diploma (10), A. E. Coleman, Stonehouse; diploma (7), W. Clayden, Plymouth.

Class O (Postcards, four on one mount).—1 (24), F. Judge, Hastings; 2 (15), F. W. Becken, Cowes, I.W.; 3 (12), T. C. Beynon, "Cheriton," Newbury, Berks; diploma (21), J. H. Saunders, 67,

Green Road, Leeds; diploma (13), T. C. Beynon, Newbury, Berks; diploma (5), E. T. Clark, The Vicarage, Newnham-on-Severn.

Class R (Miscellaneous, for Juniors under Eighteen).—1 (3), C. A. W. Duffield, School House, Maidstone; 2 (13), Jack Perrin, 6, Westfield Place, Halifax; 3 (2), C. A. W. Duffield; diploma (7), E. Jarvis, Plymouth; diploma (8), H. Hill, 12, Queen's Gate, Stoke, Devonport.

Class S (Miscellaneous).—1 (10), E. Seymour, 2, The Parade, Watford, Herts; 2 (4), C. J. King, Scilly Isles, Cornwall; 3 (16), E. W. Hearn, Plymouth.

BURNLEY CAMERA CLUB.

THE sixth annual exhibition of this club was opened at the Assembly Hall, Mechanics' Institute, Burnley, on Thursday, November 16, by the Mayor of Burnley (Councillor H. Emmott). Over 500 exhibits were on view, and the judges, Messrs. W. R. Bland and Alex Keighley, made the following awards:—

Open Classes.—Plaque, "Repose," J. C. Batkin; plaque, "A Stormy Home-coming," Arthur Smith; plaque, "Their Ever-moving Home," David Murray; (hon. mention) "Downland," J. S. Atherton; plaque, "The Outcast," G. R. Henderson; plaque, "Portrait Study," P. G. Terras; (hon. mention) "Robinson Crusoe," T. Lee Syms; plaque, "Until the Day Breaks," S. G. Kimber; (hon. mention) "The fire is out," etc., John Ritchie; plaque, Fred Judge; (hon. mention) Dr. J. W. Ellis; (hon. mention) Dr. George H. Rodman.

Local (12 Miles Radius).—Plaque, "Amid the Encircling Gloom," F. Pinder; plaque, "Old Houses, Norwich," Dr. E. R. Ivatts; (hon. mention) "The Moorland Church," J. S. Atherton; plaque, "Portrait of F. J. Grant, Esq.," F. Pinder; plaque, "A Reverie," C. I. Faunthorpe; (hon. mention) "A Normandy Dame," A. A. Bellingham; plaque, "Old Archway, Norwich," Dr. E. R. Ivatts; plaque, "Norman Aisle, Ely," J. P. Howe; (hon. mention) "Hawk-head," A. Plunkett; plaque, J. J. Hartley; plaque, A. A. Bellingham; (hon. mention) J. Emmott.

Members' Classes.—Plaque, "Lengthening Shadows," Dr. Crump; plaque, "The Langdales," Dr. Crump; plaque, "The Shadr Pathway," J. R. Richardson; (hon. mention) "The Open Door," W. E. Dean; plaque, "Figure Study," H. Rushton; plaque, "Evening Mists," A. Stell; (hon. mention) "Gleams of Sunshine," J. R. Richardson; plaque, A. A. Bellingham; (hon. mention) P. Brotherton; (hon. mention) W. E. Dean.

A feature of the exhibition was a loan collection of the works of Mr. Alex Keighley.

THE "Business Man's Magazine" (monthly, 6d., from Thanet House, 231 and 232, Strand, London, W.C.) has its vocation written in its title, and takes a big view of its duties. In fact, we would like to see it descend from schemes which only Napoleons of industry would care to undertake, and dwell upon the endless petty problems of the small business man. There must be an immense field for a periodical wholly on these lines. Two co-related items in the contents of the "Business Man's Magazine" we must not omit to note. There is an article on the proper method of typewriting, and a series of articles classed as "Tabloid Systems." But the coined word appears without italics, and probably the editor has by this time seen a good specimen of a typewritten letter—one from Messrs. Burroughs, Wellcome.

THE Hastings and St. Leonards Photographic Society has issued a useful "Members' Handbook" for 1905-6. Full particulars concerning the Society are given, and other matters of interest to the members. The hon. sec. is H. Walter Llanstephen, Fearon Road, Hastings.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents were made between November 6 and 11.

COLOUR PHOTOGRAPHY.—No. 22,725. Process of producing coloured photographs. August Zimmermann, 24, Southampton Buildings, Chancery Lane, London, for the Chemische Fabrik auf Actien vorm E. Schering, Germany.

MATERIALS.—No. 22,735. Improvements in photographic pictures, in the process of making them, and in the plates therefor. George Nicolas Piper, 47, Lincoln's Inn Fields, London.

APPARATUS.—No. 22,868. Improvements in photographic apparatus. Walter William Fiddes, 49, Cranbrook Road, Redland, Bristol.

LANTERN-SLIDE PRINTING-FRAME.—No. 22,898. Improvements in lantern-slide printing-frames. George Russell Nicholls, 48, Crescent Road, South Norwood, London.

PRINTS.—No. 23,109. Improvements in the production of photographic and other prints. Josef Rieder, 7, Southampton Buildings, Chancery Lane, London.

FILM AND PLATE HOLDERS.—No. 23,226. Improvements in photographic plate and film holders. Pietro Torrani, 7, Southampton Buildings, Chancery Lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

FOCUSING ATTACHMENT.—No. 24,183, 1904. The patent is for a system of focussing up to the moment of exposure, utilising for this purpose the camera lens, which is brought in front of a focusing screen and returned to its position in front of the plate at the instant of exposure. Automatic capping of the plate while the lens is used on the finder is provided. A. J. Boulton, for Albin Perlich, 3, Tischimier Strasse, Dresden, Germany.

REFLECTOR CAMERA.—No. 25,496, 1904. The chief claim is for a reflex camera, of which the shutter works by a double action, (1) covering the lens, which remains closed until the mirror is raised clear of it, and then (2) exposing, by opening and closing the lens aperture. These movements are effected by a single movement of the simple release. Houghtons, Ltd., 88-89, High Holborn, London, E.C., and Walter Dockree, 80, Clarendon Road, Hoe Street, Walthamstow, Essex.

DIAPHRAGMATIC SHUTTER.—No. 2,874, 1905. The patent is for a lens shutter, which is operated for time exposures by a pinion and lever gear concentrically arranged about the lens, in such a manner that the shutter blades are moved after the expiration of a previously determined time of exposure, by means of a toothed ring moving with a given speed and provided with stops for releasing the lever gear. Further, if desired, the turning of the toothed ring in the opposite direction may be caused to regulate the speed of instantaneous exposures. A. J. Boulton, for Alfred Lippert, 35, Herbel Strasse, Dresden, Germany.

PLATE HOLDER.—No. 5,198, 1905. The patent is for a plate holder, consisting of a wire handle made in such a way as to form a spring in the centre of two loops which are adapted to receive the thumb and finger. The wire and plate connecting the two bars are at right angles to the handle, and are secured together in such a way as to form a hinge. The drawing together of the loops causes the bars or arms, extending outwards from the hinge, to expand, while releasing them causes the arms to grip the inserted plate, by reason of the spring, and the recesses on the ends of the

arms. To prevent the plate from moving in the opposite direction a lip is provided upon the bottom edge of the hinge plate, or

a recess formed in the two bars at this point. William Taylor, 13, Brunswick Square, Camberwell, London, S.E.

MASKS FOR COMBINATION PRINTING.—No. 12,310, 1905. The invention consists in connecting the usual mask and the screen to form, as it were, a pocket into which the sensitised paper is inserted or slid, this pocket being open at two sides, or only at one, a

Fig. 1.

desired. One form—viz., with the pocket open on two sides is shown in the drawings, Fig. 1 showing the pocket with the mask bent over in a forward direction, and Fig. 2 the same with the screen in front. The mask *a* is secured, for instance, by adhesive to the screen *b* at the edges *d* and *g*, whereby the pocket is produced as mentioned above. When using the device, the sensitised paper, postcard or the like *h* is placed in the pocket with the sensitive side directed towards the mask *a* (Figure 1), and printed

Fig. 2.

by exposure, whereupon the paper (*h*) is turned through 180 deg. and so placed in the pocket that the surface left free by the mask is brought behind the aperture *b* of the screen *b* and the photographic negative *k* placed between the paper *h* and the screen *b* (Figure 2). As the already exposed part is covered by the screen *b*, at the second exposure the photographic picture is printed into the frame previously printed by the mask. Richard Hoh and William Hahne, 6, Reichstrasse, Leipsic.

PRINTS ON METAL.—No. 14,410, 1905. The patent is for a process of applying pictures to a metal support and fusing with the latter, into one mass. The inventors use the powder process for preparing the print. The powdering of the picture is effected with pure white silver in a pulverized state by means of a brush,

whereupon the glass plate on the side carrying the sensitized layer is covered with collodion of 2 per cent. When the collodion layer has dried, the picture-film with the collodion layer is cut to the desired size. The removal of the film from the glass plate is effected in a bath of 300 grammes distilled water with 10 grammes ammonia. The loosened film is then placed in a bath of distilled water and carefully spread by means of a brush over the metal plate or article to be ornamented. After drying, the plate is heated over a gas flame or in a furnace until the collodion layer is removed and the photographic picture is completely united with the metal article. Emil Jabulowsky and Armand Bourguin, 5, Emilienstrasse, Pforzheim, Germany.

EXPOSING PLATES AND FILMS.—No. 15,958, 1905. The patent describes a number of modifications in the inventor's dark slide, and envelopes for the exposure of plates or films. The light drawings are necessary for the proper understanding of the specification. George Wishart, High Bush Hill, Cambuslang, Lanark.

The following complete Specifications are open to public inspection before acceptance under the Patents Act, 1901.

ROLLING-UP FILMS.—No. 22,104, 1905. Societe Anonyme "Periphote and Photorama."

CAMERA ATTACHMENTS.—No. 22,590, 1905. Attachments for photographic cameras. Wladimiroff.

CATALOGUES AND TRADE NOTICES.

CHRISTMAS Greeting Postcards.—The Birmingham Photographic Co., Ltd., Criterion Works, Stechford, Birmingham, send us samples of the new series of full-size postcards, printed on the address side with a variety of attractive designs suitable to the Christmas season. The cards are made up in 6d. packets of twelve P.O.P., nine bromide or nine Celerio (gaslight), and are also sold in grosses and thousands.

A NUMBER of circulars describing and illustrating new introductions reach us from the firm of Carl Zeiss, 29, Margaret Street, London W. They relate to "Tele Adapters for Hand Cameras," "Yellow Screens," The Zeiss "Pack-Slide," and the "Universal Palms."

A NEW Nernst lamp has been designed by Mr. R. W. Paul, 68, 1 to 300 candle-power, according to the voltage. The price of the end to end, takes a current of one ampere, and gives a light of from lamp, complete with support and combined plug and resistance holder, is 18s.

"KLITO" AND "BRITON" DAYLIGHT ENLARGERS.—Both these enlarging cameras are made by Houghtons Ltd., and they are not only cheap, but appear to be excellently made. They are of fixed focus, and a lens, dark slide, and capping device are included. Both enlargers are made of wood throughout, and the "Briton," which is the cheaper of the two, is a well-made piece of apparatus, selling at 7s. 6d. for enlarging from quarter-plate or smaller, to whole plate, or 13s. 6d. from quarter-plate to 12 by 10. The "Klito" can be taken to pieces for packing and carrying, etc., which will be found a great convenience when travelling. It is slightly more expensive than the "Briton," but is well worth the money.

THE North Middlesex Photographic Society is holding its seventeenth annual exhibition of members' work from Thursday next, November 30, to Friday, December 1, at Hanley Hall, Sparsholt Road, Crouch Hill, N. The exhibition opens at 7 p.m. on the Thursday and Friday, and at 3 p.m. on Saturday. Residents in the north of London might seize the opportunity of making themselves acquainted with the numerous advantages offered by the North Middlesex for its subscription of 5s.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Nov.	Name of Society.	Subject.
21.....	Royal Photographic Soc.	House Exhibition by the Postal Camera Club. Inauguration by Mr. J. C. Warburg.
21.....	Colne Camera Club.....	Visit of Nelson Photographic Society.
21.....	Aberdeen Amat. Photo. Assn.....	"Enlarging." Demonstrated. Messrs. Borthwick and Anderson.
24.....	Nelson Photographic Society ..	Visit to Colne Camera Club.
24.....	Hampstead Scientific Society ..	"Development for Beginners." Demonstrated. Mr. H. N. Smart.
24.....	Watford Photographic Society ..	"Principles of Composition" (affiliation lecture). Mr. W. E. Tindall, R.B.A.
24.....	L.C.C. Staff Camera Club	"Stand Development." Discussion.
24.....	Barrow Naturalists' Field Club.	"The System of the Stars" (Clusters and Nebulae). Illustrated. Rev. T. E. R. Phillips.
25.....	Southampton Camera Club	The Annual Exhibition closes.
25.....	Glasgow Eastern A.P.A.	Annual Exhibition Open.
25.....	Sunderland Camera Club	Exhibition of Members' Work.
27.....	Hastings and St Leonards P.S.S.	"Palestine." Mr. J. J. Butler.
27.....	Wildes Photographic Society.....	"Holidays in the Highlands." Mr. E. MacDonald.
27.....	Barrow Naturalists' Field Club ..	"A Trip to Portugal." Mr. H. Rehl.
27.....	Scarborough and Dis. Ph. Soc. ..	Lecture. Mr. T. F. Brogden.
27.....	Dewsbury Photo. Society	Demonstration. Mr. J. E. Chadwick.
27.....	Luton Camera Club	"Practical X Ray Photography." Demonstrated. Dr. F. Seymour Lloyd.
27.....	Wandsworth Camera Club	"Rotograph Bromide and Roto Gaslight Papers, &c. Demonstrated.
27.....	Wallasey Amat. Photo. Soc	"Treatment of Negatives." Mr. W. Hayes.
27.....	Oxford Camera Club	"Bichromate as an Intensifier and Reducer." Mr. H. M. J. Underhill.
27.....		"A New Method of avoiding Contrasts in Negatives." Mr. G. W. Norton.
23.....	Royal Photographic Soc.	"Spectrum Grating Replicas." Mr. Robert James Wallace.
24.....	Worthing Camera Club.....	Lantern Slide Demonstration. Mr. N. L. Watts.
28.....	Manchester Amat. Photo. Soc.	Discussion on a "One Man" Show of Pictures, the work of Mr. T. Longworth Cooper.
28.....	Darlington Camera Club	"A Trip to Flower Photography." Mr. G. J. Bartholpe.
28.....	Glasgow Southern Photo. Assn.	Selection of Slides for Paisley.
28.....	Gateshead Camera Club	"Slow Contact Printing." Messrs. Wellington and Ward.
28.....	Hackney Photographic Society ..	Members' Sale.
28.....	Bristol Photographic Club	Notes on Re-Touching and "Faking."
28.....	Nelson Photo. Society	Mr. J. S. Guthrie.
28.....	Barrow Naturalists' Field Club ..	"Some Beauty Spots in England." Mr. H. Beetham.
28.....	Osley & Dis. Cam. & Art Soc.	Photography Prize Slides Exhibition.
28.....	Birmingham Photo. Society ..	V.P.C. Members' Portfolio Exhibition.
28.....		Amateur Photographer Prize Slides, 1905.
28.....	Thornton Heath Photo. Soc. ..	"Mud Island and its Flats." Illustrated. By one of them.
28.....	St. Helens Camera Club	Focus Prize Slides.
28.....	Coventry Photo. Club	"Fantotype."
29.....	G.H.R. Mechanics Institution...	Focus. "Stories without Words."
29.....	Leicester & Leicestershire P. Soc.	"Gaslight Papers." Beginners' Lecture. Mr. W. B. Woodland.
29.....	Society of Arts.....	"The British Association in South Africa." Sir William H. Preese.
29.....		K.C.B., F.R.S.
29.....	Leeds Camera Club.....	"Velox and its New Applications." Demonstrated. J. J. Griffin & Sons.
29.....	Edmonton and Dis. Photo. Soc.	"Rotograph Bromide" and "Rotox." Demonstrated.
29.....	Croydon Camera Club.....	Discussion on the Exhibition. Prize-winners will be invited to give explanation of their Methods of Working.
29.....	Tricklewood Photo. Society ..	"Tabloid" Brand Photographic Chemicals. Demonstrated. Messrs. Burroughs Wellcome & Co.
30.....	Liverpool Amateur Ph. Assn.....	"Over Mountain, Lake, and Lagoon." Mr. James Shaw.
30.....	Herragote Camera Club	Members' Night.
30.....	Balham Camera Club	"Gaslight Printing." Mr. G. W. Beninson.
30.....	Hull Photographic Society	"Negative Making." Demonstrated. Mr. J. Hollingworth.
30.....	Glasgow Southern Photo. Assn.	Annual Visit to the Photographic Section of the Paisley Polytechnic Institution: Joint Display of Slides, etc.
30.....	Wimbledon and Dis. Cam. Club ..	Slides in the "Summer Rambles." Lecturette Competition to be judged.
30.....	Pudsey and District Photo. Soc.	"Velox and its new Applications." Demonstrated. Mr. W. Sadler.
30.....	North Middlesex Photo. Soc.	Annual Exhibition.
30.....	Darwen Photo. Association.....	Photography Prize Slides.

MEETINGS OF SOCIETIES FOR NEXT WEEK (Continued).

Nov.	Name of Society.	Subject.
20.	Rodley, Farsley, & Calverley Dis.	"Printing-out Paper." Mr. Gascoigne.
21.	Richmond Camera Club.	"Orthochromatic Photography." Demonstrated. Messrs. Elliott & Sons.
22.	London and Prov. Photo. Assn.	Discussion on Stereoscopy. Mr. D. W. Hart.

CRIPPLEGATE PHOTOGRAPHIC SOCIETY.—On November 13 Bertram C. Wickison gave a practical demonstration of enlarged negative making before the members of this society. After pointing out the importance of having the original negative carefully spotted and all possible blemishes removed, and being sure that the picture would be improved by enlarging, the lecturer went on to impress his listeners with the necessity of the positive being a good one, as on that depended entirely the character of the enlarged negative. It should be fully exposed, soft, and full of detail in the deepest shadows. Mr. Wickison discussed the various methods of making the positives, the carbon positive on glass being grainless and in every way desirable; but pointed out that for these negatives carbon was impracticable, owing to the flatness and want of sufficient contrast the process gave. Against enlarged positives little could be said; cost was the great drawback to their general use. For combination printing he strongly advised that a good P.O.P. print be made from the desired negative, and this copied without toning or fixing in the usual manner, or with a large camera to the actual size desired. He advised the use of a fine-grain, ordinary plates using as a developer for the positive:—

Rodinal, 25 min.

10 per cent. solution of pot. brom., 5 min.

Water to 1 oz.

and for the enlarged negative a pyro-soda developer of normal strength. He also pointed out that for the worker not used to large negatives the time method of development was an advantage, as the exposure being known, less errors of development were likely to ensue.

EDMONTON PHOTOGRAPHIC SOCIETY.—On Wednesday, the 15th, Mr. Ernest Human lectured before the above society upon "Colour-sensitive Plates." He said that the gradation of tones, even more than the variety of colour, was what charmed the eye in a country scene, and when we attempted to record such a scene we must preserve the gradations if we would keep any suggestion of the original charm. A false note in tone was to the artist as offensive to the eye as a false note in sound is to the ear of a skilled musician. Referring to the screen or light-filter, he said that these were of the highest importance, because if one was to obtain the full value of their use they must be properly corrected to the plate, and not, as some had it, to the light. Further, to call them by the terms 3, 6, or 10 times was a misnomer, because a screen when used with one brand of plate might require 10 times, whilst with another brand it might fall to 7 or 8, or rise to 12 or 15. Screens must be of a bright yellow colour, and should not be of an amber or brown cast, because such colour cut off part of the very light one wanted to pass. A false notion existed amongst amateurs that colour-sensitive plates easily fogged. If such plates did fog in the dark room, it meant that they were being worked in an unsuitable light, and to blame the plates under such conditions was as bad as blaming the ordinary special rapid plates because they fogged in a yellow light that might be quite safe for process plates. After having summed up the subject, a series of some 70 slides was put through the lantern showing work done upon various brands of colour-sensitive plates, which largely went to show that correct rendering of colour could be easily obtained when care was used.

HULL PHOTOGRAPHIC SOCIETY.—Mr. G. F. Bristow, junr., gave a demonstration before the members of this society last week on

"Making and Working up Bromide Enlargements." He described his method of making large developing dishes. They were made out of a box about 17½ in. by 12½ in., sawn so as to make two dishes 3 to 4 in. deep. These were lined with calico, the bottom and two ends being glued first, the side pieces being taken off temporarily. The sides were then glued, put on (the calico pulled through the corners), and nailed together. It was then necessary to give the inside two coats of glue-size, and afterwards, as they dry, two coats of white paint, and one or more coats of enamel were given. For direct enlarging the negatives should be thin and full of detail. Hard and dense negatives required increased exposure and diluted developer. The lecturer usually toned his enlargements by the hypo-alum process, and he had found that the best brown and sepia tones are brought about by previously developing the enlargement with hydroquinone. This being slow in action, gave full control and every opportunity for local working up by the aid of a camel-hair mop brush. His formula was as follows:—

Stock solution:—1 oz. of caustic soda to 9 oz. water

No. 1	Hydroquinone	1 oz.
	Potassium metabisulphite	15 gr.
	Potassium bromide	75 gr.
	Water	30 oz.
No. 2	Sodium sulphite	3 oz.
	Caustic stock solution	3 oz.
	Water	30 oz.

Use equal quantities of No. 1 and No. 2, and for a 15 x 12 print five ounces was ample to cover the paper when previously soaked with cold water, as it is always necessary to do when working with paper above half-plate size. When fixed the print was immersed in water while the toning bath was prepared. This was made by dissolving ½ oz. alum in 10 oz. of lukewarm water, then adding 10 oz. of cold water. The prints were taken out of the water and put in this solution for a few seconds; then 5 oz. of hypo., already dissolved in 15 oz. of water, were mixed with it, making 55 oz. altogether. This should be done in a galvanised iron tank or dish 4 to 6 in. deep, supported at each end with a block of wood or a brick. In the centre was placed a gas ring, and the solution was gradually heated up to 100 or 110 degrees, with the print or prints kept moving face upwards. There were signs of toning in 15 minutes, and when taken as far as desired, the prints were pinned up until cool, and afterwards washed, face upwards, in the usual way. For hypo. alum toning the papers should be amply exposed and developed fairly black, as they reduced considerably in toning. The whites were well de-graded, and for the best tones 20 oz. of old solution should be added to the bath to make 55 ounces. Blisters were due to raising the temperature too quickly. Mr. Bristow also showed how to work up or strengthen foreground, shadows, and clouds. He preferred to add clouds from a second negative, and improve where necessary afterwards. He powdered a little household blacklead, and by the aid of a small piece of washleather rubbed in same, and afterwards smoothed down upon a piece of blotting paper until the correct tint was obtained. This was rubbed on the print where required. Then what was not required, or where it was wished to lighten up any part, breadcrumbs made into a small ball were used. For sepia prints a combination of red and black chalks were mixed by the same method until the correct tint had been obtained.

ROYAL COLLEGE OF SCIENCE PHOTOGRAPHIC SOCIETY, DUBLIN.—A general meeting of this society took place at the College last week. The following officers were elected for Session 1905-6:—President, Mr. G. H. Pethybridge, Ph.D.; treasurer, Mr. J. Taylor, B.A., A.R.C.Sc.I.; hon. secretary, Mr. W. L. Rutledge; committee, Messrs. J. F. Crowley, J. N. Down, P. McGinnis, P. J. Smith, G. A. Watson.

CLEVELAND CAMERA CLUB.—On Wednesday of last week, at the invitation of Messrs. Hood and Co., Limited, Middlesbrough, a

large gathering of members of this club met at the Photo-Process Works of the above firm, and were shown over the works by the managing director, Mr. Harold Hood. To illustrate the work more clearly the various steps in the making of a process block were illustrated in a very practical and able manner, and eventually prints were pulled and handed round from the block made during the evening.

BOLTON AMATEUR PHOTOGRAPHIC SOCIETY.—On Thursday, November 17, the R.P.S. lecture by Mr. H. T. Malby, on "Flower Photography," was read by one of the members. The desirability of guarding against over-correction was emphasised, and slides from correctly exposed negatives taken with iso plates and screens, necessitating not more than three times the normal exposure, fully bore out the lecturer's contention. In the arrangement of flowers to be photographed, care should be taken not to crowd the composition, and not to arrange the subjects so as to produce a top-heavy appearance. As a means of supporting grasses, individual flowers, shoots of brambles, etc., the use of a lead strip of $1\frac{1}{2}$ in. wide, doubled upon itself at intervals to pinch the stems, was suggested.

RICHMOND CAMERA CLUB.—At a meeting on Thursday of last week Dr. Rodman gave a lecture on "Photomicrography," with a practical demonstration of the work. The lecturer said:—The requisites are a microscope and a camera body capable of the necessary extension, and having these, the work can be conducted in a well-warmed and lighted room. The microscope should be a monocular with a firm, steady stand capable of being brought into a horizontal position, and provided with a fine adjustment, so as to ensure true and crisp focus. The rigidity of the apparatus is of prime importance, as upon it depends to a great extent the success or the reverse of the picture. The table or bench upon which the apparatus is placed should also be of considerable solidity. For high magnification it may be necessary to use a concrete floor, as with the shaking that even a passing heavy vehicle in the street may produce the results may be marred. Dr. Rodman stated that he has no such floor, but that he uses a fixed bench built into the wall of his dark room. The microscope-stand that he employs cost years ago about five guineas only, and probably at the present time for the same sum an even better instrument could be obtained. The objectives must be of sound construction, and should ensure a good flat field, with an absence of any falling away at the edges. They may be achromatic or apochromatic, in order to get a colourless image, with all the rays brought to a common focus. With the former an ordinary eyepiece may be used, but with an apochromatic objective it is necessary to employ a compensating eye-piece. It is more particularly in high magnifications, say above 400 diameters, that apochromatic lenses are required. It is an open question whether an achromatic lens should be used with or without an eye-piece. With a one-inch objective and no eye-piece an extension of not less than 3ft. 2in. from the ground glass to the object is required, which makes focussing difficult, whereas when using the same objective with an A eye-piece about 1ft. 9in. is ample. The amount of magnification is somewhat different in each case. In working for a certain magnification it is better to use a low eye-piece with extended draw tube rather than to use a shorter tube with a higher eye-piece. The lower the eye-piece used the more perfect and better illuminated the object will be on the ground glass screen. For a camera Dr. Rodman uses a Newman and Guardia "Special B.," which allows of sufficient extension to cover a quarter-plate. The camera and microscope must be placed on a true axial line. The next matter for consideration is the source and method of illumination. Several distinct sources of light may be employed—sunlight, oil lamps, incandescent gas, limelight, acetylene gas and electricity. When employing sunlight a heliostat must be

used—it is very rich in actinic rays, and can be used as a monochromatic light by the interposition of a screen that will allow of coincidence of the visual and actinic foci of the objective, but it is too uncertain a source in the English climate. Oil light is too poor. Incandescent gas is not to be recommended, as the light does not approximate to a point, which is an important consideration. Lime light is satisfactory if the microscope lens and slide are suitably protected against the heat. Acetylene gas appears to have possibilities, as the light is of good actinic value, but the electric light is the best, and most of Dr. Rodman's work has been produced with a $\frac{1}{4}$ -ampere Nernst lamp. Illumination may be either direct, oblique, or by reflected light, according to the nature of the object. The plate employed must be backed, and the use of a coloured screen gives the best results. The length of exposure depends upon the amount of light and also upon the colour of the object. An object of average thickness seen through a 1-in. objective with A eye-piece and an isochromatic screen can be photographed with a $\frac{1}{4}$ -ampere Nernst lamp in from ten to twenty seconds on Imperial special rapid plates; for higher magnification a longer exposure is required. Practice can alone make perfect in this respect. The negative must be clean and full of detail, with plenty of contrast, having a good opaque background, which will print as a perfect white. The developer must be strong in pyro—as much as five or six grains of pyrogallie acid should be used to the ounce of developer.

News and Notes.

THE Scottish Photographic Federation has issued a very complete list of judges for exhibitions and competitions, lecturers, demonstrators, and lectures and slides for circulation. This is a separate publication to the S.P.F. Blue Book, and sums up just those particulars that the hon. secs. of the Federated Societies want to know when compiling their winter programmes. The list is in the form of a handy booklet, and enough material is provided by the scheme of interchange of lectures and lecturers to fill half a dozen syllabuses. The secretary, John B. MacLachlan, will supply all further information.

THE Free Photo Fraud Again.—A correspondent to the "Birmingham Daily Gazette," writes complaining of the free photo dodge practised in his district. He says:—"Some few weeks ago a very charming young lady called at my home whilst I was at work, saw my wife, and begged very hard to let her take away a photo to have it enlarged free of cost, on the condition that my wife hung it up just to advertise their business, and, says the lady canvasser, 'at any time you should want it framed our firm would be pleased to do business with you.' My wife was then asked to sign a paper without any explanation whatever. A few days later a gentleman, one of an American firm, called with samples of picture frames. My wife told him she did not want one. A few days later I received a letter to say that their agent had called, and that my wife had refused to select a frame, and unless I either called or wrote to them in five days they should frame the enlarged photo with their usual 50s. frame, and put the matter in their solicitor's hands to collect the same, with costs, etc. I treated their letter with contempt. About a fortnight later, whilst I was at home, another of the American firm called. I treated him for what he was worth, and quickly showed him the street. Why I write this is to warn working men's wives not to sign anything from anybody. Let the husbands do the signing business; it will save the police court proceedings, and very likely county court proceedings later on."

A CAMERA and Optical Lantern Society has been formed in connection

tion with the Walkley (Sheffield) Conservative Club. The president is W. J. Booth; hon. treasurer, G. D. Harrison; and hon. sec., S. Hall-Downing, 292, South Road, Sheffield.

THE Second American Salon.—Although the British and Italian pictures have been delayed in the New York Customs House, the preliminary jury has gone through the American and other prints, reducing their number to six hundred, from which the jury of painters have selected a hundred and seventy-five for the exhibition. It was expected that the delayed works would be clear of the customs by November 19, and a special sitting of the painters' jury was arranged for that date, to select, and also to decide on the pictures to be purchased for the permanent collection.

STATIONERY, whether note-paper, price-lists, or the seductive booklet of invitation, being an all important item in a business which is professedly directed by good taste, a photographer may be advised to "grapple to his heart with hooks of steel" any printer who will take pains to produce attractive literature. One firm that may be named for the above ordeal of friendship is Messrs. Walter Pearce and Co., St. George's Press, Brentford, W., a selection of whose folders, business cards, etc., bears uniformly the impress of good taste and experience in the production of a booklet which is not thrown away by the recipient. In fact, by a coincidence, during a visit to the Midlands, we were shown by a friend a little booklet issued by a local photographer and preserved on our friend's mantelpiece as a reminder: the identical booklet we find among Messrs. Pearce's specimens.

WITH the new year the "Animal World," which has been published monthly by the R.S.P.C.A. since 1869, will appear with many new and attractive features—one of these should appeal especially to our readers. In the January number will appear a monthly photographic competition—divided into two classes, with a prize for each class—Class A, for those over sixteen years of age; Class B, for those under that age. The photographs for competition must be of animal subjects, and must depict an incident, or make a story. The December number of "Animal World," published on November 25, will contain full particulars of this competition.

MR. ROBERT F. SHERAR, of 6, Ann Street, Edinburgh, writes us in reference to his lecture on "Linear Perspective," given before the Glasgow Architectural Association, and reported in our issue of November 10. He says: "Many peculiarities of perspective in photography are blamed on the 'lens,' while as a matter of fact the same perspective is obtained by whatever lens is used. If you change your position or the position of the lens you give a different view, but from the same station-point all lenses give the same perspective; a different image of this perspective appearance, however, may be got by varying the other fundamental conditions of perspective projection, such as the angle of picture plane (or photographic plate), etc." Mr. Sherar has written an admirable little book entitled "Perspective Tables," and although it is primarily intended for use by architectural draughtsmen, special reference is made in it to the use of the camera and lens, and the points dealing with the use of rising and cross fronts, etc., are very ably demonstrated. Every architectural photographer should study this little work.

Commercial & Legal Intelligence

RE GEORGE FENWICK, PHOTOGRAPHER, BURTON.—This debtor appeared for his adjourned public examination at the Burton Bankruptcy Court on Wednesday of last week. The statement of affairs filed by the bankrupt disclosed liabilities amounting to £99 2s., and assets estimated to produce £19 7s. 7d., less preferential creditors £5 7s., leaving a deficiency of £85 1s. 5d. The case was again adjourned, the Official Receiver not being satisfied with the account given by the debtor of his book debts.

MORE FREE ENLARGEMENTS.—At the Westminster Police-court on Wednesday, two young servants from Sloane Gardens, Chelsea, applied for advice as to the detention of their photographs obtained from them by a canvasser, who represented that enlargements would be made gratuitously just to advertise a new branch business to be opened in the locality. Proof enlargements of the pictures were subsequently shown the applicants, and extortionate demands made for frames, which had not before been mentioned. The girls said that when they refused to pay for frames the return of their original photographs was refused. Sergeant Avery, the warrant officer, said that there had been several complaints of this kind, and in some instances young people had been frightened into making payments. The Judge thought the police might with advantage make a little inquiry into this business, and said that a summons would issue if the girls' photographs were not very promptly returned.

A BOOK QUERY.

To the Editors.

Gentlemen,—Perhaps one of your readers can help me in the following:—I have a volume on "Practical Chemistry" published in Orr's Circle of the Sciences. Date on the full compound title page, 1856; pages 101 to 304 on "Photographic Art." Title page gives name of Marcus Sparling, but the foot of page 304 says W. Sparling. I have seen a separate copy of the photographic portion of the volume, but did not look at the numbering of the pages. The list of the Photographic Club (London) library gives the date as 1859. What I want to know is: (1) Whether my copy is the original edition? (2) Whether the separate volume is a stereotype, a reprint, or a revised edition? (3) How many editions the book went through?—Please oblige, C. R. W.

27, Mostest Road, Observatory Road, Cape Colony,
November 1, 1905.

EMULSION INVENTIONS.

To the Editors.

Gentlemen,—Your irate correspondent who signs himself "O" should understand that Mr. Burgess was requested to give a paper on "The History of Gelatine Dry Plates" because someone supposed that he ought to know more about it than any other person. The paper consists of a plain statement of facts. If that is to be compared to sounding brass, he is guilty of trumpeting, and owns it. Some people prefer fiction to fact, but dare not say so. There was no intention of casting a slur upon the name of Traill Taylor. The worst thing anyone was accused of was carelessness or forgetfulness on this particular occasion. It was proved by quotations from his own journal that he had overlooked important facts. Perhaps he did not know they were there. But not a syllable was said that could be fairly interpreted as impugning his honour. No doubt Mr. Taylor had persuaded himself that he was right, and he would not condescend to listen to a mere nobody. Nevertheless, his action was challenged at the time the testimonial to Dr. Maddox was proposed, but the voice of right and reason, not for the first time by many, was drowned by the action of a triumphant majority. It is not in human nature to see the golden nature of silence when historical accuracy is at stake.

As to the sneers about colour photography, and the elaborate attempt to raise a prejudice without the shadow of a cause, be it said that they will soon speak for themselves. It is intended to send an advertisement to this journal early in the coming year, stating how and on what terms they may be obtained. And that no one may be deceived it will be distinctly stated that hand work plays an important part in the process. The problem to be solved is, how to reduce retouching to a minimum without sacrificing artistic effect. Colour, of course, is not produced by the chemical action of light, but the gradations which make the picture are. It is the opinion of many who have seen the experimental specimens that colour values are rendered more correctly by this process than by any other. It will in no way compete with the three-colour work, but will be at home in the ordinary studio.—I am, yours faithfully, J. BURGESS.

71, Stillness Road, Forest Hill, S.E., November 20, 1905.

To the Editors.

Gentlemen,—In the report of his paper on "The History of Gelatine Emulsion Plates," read before the London and Provincial Photographic Association, which appeared in your issue of November 10, Mr. J. Burgess relates what he terms "the correct version of a tale which has been very much garbled and distorted, not intentionally," he is quite sure, "but through carelessness!"

Regarding Mr. Burgess's claim that he invented bromide paper, is he aware that my father, Sir Joseph (then Mr.) Swan, patented it in 1879?

Assuming that Mr. Burgess claims the invention prior to 1879, why did he not oppose the granting of the patent, or contest its validity?—Yours faithfully,

DONALD CAMERON-SWAN.

November 15, 1905.

[Sir Joseph Swan's application for patent was made on July 22, 1879, and included even "printing at a uniform and rapid rate; the sensitive paper may be used in long bands, and by means of automatic mechanism may be moved on step by step periodically through a space equal to the width or length of the print, the negative being screened from light during the movement."—Eds. B.J.P.]

TONING BROMIDES.

To the Editors.

Gentlemen,—I have read with much interest your article on "toning bromides," but am somewhat surprised at your strictures on the Somerville platinum process. I have toned a large number of prints by this method, and have never found the slightest signs of fading, prints toned three years ago and continuously exposed to good strong light being now, to all appearance, unchanged.

One thing, however, is of absolute importance—viz., the complete washing after fixation, otherwise there is the danger of the high lights assuming the "pale lemon colour" mentioned in your article.

Provided the above point is carefully watched, and the proportion of mercury to platinum given in Mr. Somerville's formula is not exceeded, it is difficult to understand why prints toned in this way should not be as stable as any other silver prints toned by platinum.

Perhaps the subject may be sufficiently interesting to you to warrant an inquiry into the history of those prints which have failed.—Yours truly,

W. B. CRICHTON.

73, Holly Avenue, Newcastle-upon-Tyne, November 14, 1905.

[We are obliged to our correspondent for his letter, for actual experience is always valuable. With regard to the prints to which we have referred, they were treated precisely as advised by Mr. Somerville, and with a strict adherence to the formula. The following passages from "Toning Bromides," a book written by Mr. Somerville, are of interest:—"Later experiments with my own formula have shown that the mercury simply acts as the reducing agent of the platinum, and the presence of the citric acid prevents any permanent combination between it and the silver, also, at the same time, preventing a combination with the gelatine. But the sepia tone is undoubtedly produced by a combination of the platinum and silver, for, if the print be immersed in cupric bromide, the silver will be converted into silver bromide, and on treatment with hypo dissolves away, leaving a pure platinum image behind of a lighter and browner shade." Our comment on this is that the proof of the image being composed of silver and platinum alone is decidedly weak. There is no proof that mercury is not present, for it also would be bleached by cupric bromide. In the platinum process, when mercury is used in the sensitiser or developer a sepia image is obtained, and von Hübl has shown that this image is composed of a mixture of platinum and mercury, and it is but

reasonable to assume that the same chemical reactions would occur when toning bromides. Mr. Somerville's statement that the mercury merely acts as a reducing agent of the platinum, and that there is no mercury in the image is absolutely unproved. Again, he says, "if the toned print be immediately subjected to an ordinary bromide paper developer, the black colour will return with great intensification; but prolonged washing will prevent this." Now, if this be true, it is absolute proof that there remains in the image a salt reducible by a developer. Therefore, the sepia tone cannot be undoubtedly produced by a combination of the platinum and silver. If the instructions are carefully followed, it is obvious that, even excluding the use of free hydrochloric acid, which the author advises, any mercuric chloride must react with the silver of the image and form silver and mercurous chlorides; we should like to see the chemical equations which will explain the absence of these unstable salts in the finished print.—Eds. B.J.P.]

THE RESTORATION OF DAGUERRETYPES.

To the Editors.

Gentlemen,—The information in your "Ex Cathedra" note of November 17 shows beyond doubt that the Daguerreotypes that have passed through my hands must have been toned, and not untoned, as I thought. If, however, untoned specimens are very rare, as your note seems to suggest, the danger of unexpectedly meeting with and destroying one in the "restoration" process is not very great. If it is possible to distinguish untoned from toned images by inspection there should be no risk, but apparently it is not very easy to detect the difference. There is nothing in the appearance of the toned image that suggests the presence of gold, but I imagine there must be some perceptible difference, and any information that will assist to identify the untoned image would be of value. So also would any hints as to the method of cleaning it. I recommend pure spirit in preference to methylated spirit, simply because it is now difficult to procure the latter free from mineral spirit, while much of the liquid sold as methylated spirit is either "finish" or some very doubtful compound.

It is regrettable that the Daguerreotype process should now be, as you say, an obsolete one. The ordinary single image may be most interesting as a curiosity, but the stereoscopic slide shows that the process is one of peculiar value. I do not know any modern process that will represent water, glass, or metallic sheen so realistically, or any one so well adapted to show surface texture. The slides must be absolutely free from tarnish to show these effects to perfection, but the time spent in cleaning them is well repaid, and, considering the rarity of such slides, it appears to me that the manufacture of new ones would be worth consideration.

It has been suggested to me that a coating of celluloid, or of some suitable transparent varnish should serve to preserve the image from tarnish. I do not know if this has ever been tried, but possibly it has, as the suggestion is a somewhat obvious one. Seeing that no traces of varnish are usually met with, I presume that experience is unfavourable to its use, but, possibly, celluloid might succeed where other varnishes have failed.—Yours, etc.,

C. WELBORNE PIPER.

November 17, 1905.

[The only way we know of distinguishing between a toned and an untoned Daguerreotype is by the appearance, and that is a little difficult to describe, except to say that the image of the latter is very feeble as compared with a gilded one. We think, however, that our correspondent will be perfectly safe in considering any Daguerreotype he may have to deal with as being gilded. We do not consider that the production of Daguerreotypes at the present time would meet

with the remotest commercial success, whether stereoscopic or otherwise. As regards varnishing them, that was suggested when the process was in vogue, but was not adopted because it marred the beauty of the picture. Moreover, varnishing is quite unnecessary, as the picture can otherwise be securely sealed from the atmosphere. —Eos. B.J.P.]

THE PERMANENCY OF MATT-COLLODION PRINTS.

To the Editors.

Gentlemen,—I have read with much interest the very useful correspondence in reference to the permanence of matt C.C. paper. In my opinion one reason why so many photographers fail to produce permanent prints on this paper is their utter disregard of two very important items in the treatment thereof—I refer to the salt solution previous to toning, and thorough washing between toning and fixing. Many workers persist in carrying the platinum toning operations on precisely as if they were toning gelatine chloride prints with gold, and matt C.C. must have more consideration. I have used a great quantity of this paper, and consider it, properly manipulated, the most permanent printing-out paper in use, but, judging from your correspondents' letters, my methods of working differ slightly from the general rule.

I never trust blotting paper, using only clean white cloth, both for drying unmounted prints and for covering when squeegeeing on to the mount. If some light frames are made and covered with well-washed sheeting or muslin in such a way as to be easily detachable for occasional washing, and the wet unmounted prints laid face downwards thereon, they will dry without curling, and will be found in excellent condition for trimming and mounting.

I never use the double bath for toning, using the platinum bath only, made up with the smallest permissible quantity of acid—nitric in preference to nitric or phosphoric—and always mixing the new bath with an equal quantity of an old one. On one occasion I found small yellow spots appear, one of which, under a microscope, showed a minute speck of cinder, which had fallen on the semi-dry print in the form of dust, probably when the fire had been attended to, and on blowing some dust from the grate on to a print, it became covered with spots within twenty-four hours. I do not pretend to know what chemical action had taken place, but on taking precautions against the dust, no more spots appeared. I may add, however, that when investigating the trouble in the first case, I found that particles of rubber, which might be used for cleaning mounts, if left on the surface of the print, quickly produce spots of a yellowish colour; but this might not occur with all makes of rubber, being probably due to some solvent used in the manufacture.—Hoping my experience will be of some help to your readers, I remain, yours faithfully,

W. SHENTON.

Grove House, 282, Bury New Road, Higher Broughton,
Manchester, November 20, 1905.

THE Southsea Exhibition.—We would remind our readers that the entries for this exhibition close on December 2, and the last day for sending in exhibits is December 6. Fourteen bronze plaques will be placed at the disposal of the judges in the Open Classes, and a special award, in the shape of a bronze salver, will be awarded jointly by the Southsea, Hove, and Southampton Societies to the exhibitor at all three exhibitions whose work shall be judged of the highest merit. The judges for the Southsea Show are Messrs. Reginald Craigie, H. T. Lilley, and H. Snowden Ward. Entry forms and full particulars will be sent by the hon. sec., F. J. Lawton, 20, Clarence Square, Gosport, Hants.

Answers to Correspondents.

- **All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*
- **Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- **Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.*
- **For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 1d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

PHOTOGRAPHS REGISTERED:—

- P. Wynne, 518, Coventry Road, Small Heath, Birmingham. *Photograph of Birmingham Football Club with Three Cups.*
- J. E. Beehan, 150, Rathmines Road, Dublin. *Photographs of V. Harris, J. Owens, the Bohemians Football Club, the Shelbourne Football Club.*
- H. Johnstone, Rockstone Place, Castle Douglas, Scotland. *Photograph of James Donan.*
- B. Bolton, Stadio, Princes Road, Weybridge, Surrey. *Photograph of St. James' Church, Weybridge, with Steepjacks Replacing Lightning Conductor.*
- E. E. Lipplatt, 2, Church Terrace, Leamington Spa. *Photograph of the Right Hon. A. Lyttelton.*
- E. J. H. Care, 284, Ashton New Road, Beswick, Manchester. *Photograph of the Manchester United Football Club, First Eleven (Season 1905-6).*
- R. E. Naylor, Ruddington, Nottingham. *Photograph, Postcard entitled, "A Souvenir of Ruddington."*
- A. C. Milne, Carcary House, Brechin. *Photograph of Careston Parish Church, Interior View.*

DRAWING REGISTERED:—

- A. C. Milne, Carcary House, Brechin. *Drawing of Careston Parish Church, near Brechin.*

TRADE NAME.—I should be obliged if you could inform me if I am doing right in trading under the name of Mora; there is a Mora, I know, at Brighton. I am opening another branch in the town, and do not wish my name to appear.—R. W. BROWN.

You would not be doing right in using the trade name of another photographer in such a way as to lead the public to imagine the business was his. Why cannot you fix on some other name to trade under if you do not wish to use your own?

A BOOK ON LENSES.—Would you kindly recommend me an elementary book on lenses and stops, and I would be greatly obliged?—R.

"Photographic Lenses." By Conrad Beck and Herbert Andrews. 1s.

A QUESTION OF COPYRIGHT.—Will you kindly inform me if there be anything in the copyright law, or otherwise, to prevent anyone copying the engravings in Charles Dickens's works and publishing the copies as postcards, etc., or enlargements?—COPYRIGHT.

There certainly is, if there be an existing copyright in the pictures. There are several different sets of illustrations to Dickens's works, and some of them are of comparatively recent date. You should ascertain if there is an existing copyright in those you wish to reproduce before copying them, or you may find yourself in trouble.

RETOUCHING (reply to "F. D.").—You smooth up very fairly, but without much distinction in your touch. Your chief fault lies in the over-working and removal of age and character marks as shown in the cabinet print. The result is much too youthful for the sitter's real age. The other study is much better, but the streak of strong lighting down the nose thins the feature, alters the shape, and is incorrect. You cannot see

such a line in life. A stronger shadow under the chin would have been an improvement, giving relief to the face, and rendering the chin less heavy. At present it appears to merge into the neck. You will make a good retoucher in time, and with greater attention paid to the modelling.

TOM W. W.—A small advertisement in our columns will almost certainly bring you in touch with those willing to sell.

T. A. M.—If you were paid, or expect to be paid, for taking the photograph, you have no copyright whatever in it. Your customer can do as she pleases with the prints. You are advised to read the article on "Copyright" in the forthcoming "Almanac."

COPYING.—I have some pictures brought to me to enlarge of Norval's Pont Bridge, S. Africa. They are marked "copyright" at the back. Have I the right to enlarge them for my customer?—**M. A. E.**

You are liable to action for infringement, as is also the person who gives you the order. Your best plan is to arrange with him in writing to indemnify from any consequences. See the article on "Copyright" in the forthcoming "Almanac."

COPYRIGHT.—I would be glad if you could give me information concerning the law of copyright on the following points:—1. Some negatives were left me (by will) by my brother, who died in January, 1899. Does the copyright for these run out in January next on the expiration of seven years from the date of his death, or does it continue for my lifetime? 2. Could negatives taken by the above, but not previously copyrighted, be registered by me now, and, if so, should this be done in his name or in my own.—**M. F. M.**

1. If the negatives were left to you without assignment of the copyright, the latter was lost there and then. Even supposing there was an assignment, the duration of copyright is only seven years after the death of the author. 2. No; the copyrights have ceased to exist.

H. M. W. (Leicester).—O. Sichel and Co., 52, Bunhill Row, E.C., or Epstein and Co., 33, Broad Street, Bristol.

WARM TONES ON WET COLLODION.—Will you kindly give me formulae that will give red, warm brown, and blue black tones to wet plate lantern slides?—**PERCY CLEGG.**

For warm brown, bleach in a bath of iodine and potass. iodide of port wine colour, and after washing, place in a bath of ammonium sulphide, 10 minims per ounce of water. For tones approaching red, tone after further washing in: Gold chloride, 1 grain; potass. ferricyanide, 60 grains; uranium nitrate, 60 grains; water, 20 ounces. A good bath for black tones is the following, due to G. T. Harris: Sodium phosphate, 50 grains; gold chloride, 5 grains; potass. chloroplatinite, 5 grains; water, 5 ounces.

PYRO.—We are unable to say. If you write to the present firm at Brighton no doubt you will obtain the information.

MASTIC VARNISH.—I should esteem it a great favour if you would kindly give me a formula for preparing (1) "Megilp" (or making same) as used in oil paintings; (2) also formula for making mastic varnish in small quantities?—**OLD GRIFFO.**

(1) Megilp is formed by mixing equal parts of strong mastic varnish and drying-oil. Another megilp is made by mixing 1 part of a saturated solution of sugar of lead in water with two parts of linseed or poppy oil. These are well stirred together, and two parts of mastic varnish added. (2) Here is a formula for mastic varnish as given by Cooley: Picked mastic, 5lb.; coarsely pounded glass, washed and dried, 3lb.; rectified oil of turpentine (lukewarm), 2 gallons. Put into a

four gallon can and agitate till dissolved. Decant the clear portion and keep for twelve months before using, as it improves with age. Of course you can reduce the quantities to suit your requirements. We may tell you that you will find it more economical to purchase these preparations than to attempt to make them yourself in small quantity.

G. MOODY.—Prints received, and will be dealt with in due course.

STUDIO ACCESSORY.—I am making a studio accessory, stone garden seat, and should be pleased if you would advise me if unbleached calico would be suitable for covering framework; also whether it would be better to stretch calico wet over the framework when covering.—**ACCESSORY.**

Unbleached calico is the best thing for the purpose. It had better be put on dry, and strain pretty tight; then, when it dries, after sizing prior to colouring, it will shrink and so become exceedingly tight.

BLEACHING BROMIDES, ETC.—1. Will you please say in this week's B.J. how to get a pen-and-ink outline sketch on a silver print, or bromide, by bleaching, etc., after sketch has been traced in by pen and ink? 2. Also please say how to obtain a clear solution of shellac, with methylated alcohol as solvent.—**I. S. T. O.**

1. Draw over the outlines in waterproof ink, and bleach the print in a mixture of potassium cyanide and iodine. You will find this formula and several others for the same purpose in the forthcoming "Almanac." 2. It is not easy. Try shaking up with powdered glass or chalk and allowing to settle; or, failing this, use rectified spirit.

I. D.—The following from the forthcoming "Almanac" gives a paste of the kind required:—Best white dextrine 1 lb., cold water make stiff paste, water 10 oz., oil of wintergreen 1 dram. Mix the dextrine and water together in small doses of each so as to ensure a mixture free from lumps and clots. Dilute with the further quantity of water, add the oil and just bring the whole mixture to the boil, when it should be like clear gum. Pour into pots, cover up, and in twelve to twenty-four hours it will be set to a hard and white paste of great adhesive power. The dextrine must be the best white: inferior dextrine remains treacly on cooling.

MESSRS. GORIS ET FILS.—The salt referred to in the paragraph on page 822 is sodium chloride, NaCl. The formula for chloride emulsion (page 828) is given in metric measure. Those for the two P.O.P. developers are as follows, in metric measures:—Page 822: Metol .32 gms., pyro .32 gms., glacial acetic acid 7.1 ccs., water 284 ccs. Page 826: A—Pyro 2.1 gms., tartaric acid 2.1 gms., water 454 ccs.; B—Potass bichromate .004 gm., water 454 ccs.

*** * NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1906.

EDITED BY GEORGE E. BROWN, F.I.C.

Published This Day.

THE whole edition of 25,000 copies of the 1906 ALMANAC is now in the hands of photographic dealers and booksellers, and the publishers request those requiring copies to obtain them from their usual source of supply.

The features of the ALMANAC are sufficiently well known, but attention may be specially directed to certain constituents of the forthcoming volume:—

1. *A Contents*, serving as a guide to the pages, and showing at a glance in which portion a given item of information is to be sought.

2. *An Index* of nearly every individual fact, formula, and paragraph, serving to take the consultant to his subject at once.

3. *Photographic Copyright*. A popular exposition of the subject in its present-day applications.

4. *Epitome of Progress*, classified and codified. A review of the year's work in technical and scientific photography; in which everything on a given subject is assembled at one place in the volume.

5. *Contributed Articles* by leading writers.

6. *A Frontispiece*, in Barnet Platino-Matt bromide paper, of Miss Billie Burke.

The Tables, Formulæ, and other features of the volume have been revised and re-arranged, and, it is hoped, will meet with the approval of every one of the 25,000 prospective readers of the 1906 ALMANAC, which in mere size, the publishers must confess, is greater than any of its forty-four predecessors.

EX CATHEDRA.

The Cape Town Exhibition.

We again take this opportunity of reminding our readers that entries for the Cape Town Exhibition must be in our hands on or before December 4 (Monday next). Full particulars were given in our issue of November 3, and we would particularly request exhibitors when sending packages or boxes to this office for transmission to South Africa, to advise us of the contents, and also to send entry forms and fees, etc., in separate letter addressed to The Editors, BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, W.C.

* * *

An Historical Mare's Nest. Dr. Murray's appeal, in the photographic Press a week or two ago, for any reference to the word "photography" prior to Herschel's use of it in March, 1839, has led a writer on photography in the "Daily Telegraph" of Friday last, to credit Niepce with the invention of the word—in a letter of May 9, 1816. An amateur contemporary in its issue of Tuesday last repeats the statement in such exactly similar words as to suggest identity of origin. Unfortunately, the statement is founded on several misconceptions, and has not a vestige of documentary evidence to support it. In the first place this letter, with many others of Niepce's, was never published until 1867 when Fouqué collected them in his "La Vérité sur l'Invention de la Photographie." In the second place, it so happens that the letter does not contain the word "photographie." It is M. Fouqué who, commenting on the fact that Niepce records his success in diffused daylight, uses the words: "Il aurait pu dès ce moment remplacer le mot Héliographie par le mot Photographie puisqu'il annonce qu'il n'est pas nécessaire que le soleil luire pour opérer" (p. 65). The writer in the "Telegraph" has only confused, in a secondhand account of the facts, what Niepce wrote, and what his very biased biographer wrote of him 50 years afterwards. Still a writer with less chaotic knowledge of the early history of photography might have remembered that to the day of his death Niepce used the word "heliography" to describe his process.

* * *

Rapid Mounting.

At a time of the year when the prompt despatch of orders is of more than ordinary importance, and when also an unusual amount of work is hoped for, and must be executed by a definite date, all the details of production need attention so that neither time nor quality may be lost, nor waste occur. Hurried work is rarely, if ever, good work, and it is poor policy to do a thing in a certain way hurriedly. Better far to devise some method of systematically doing the work so that time may be economised. Mounting particularly is one of the things that must not be hurried. Much, of course, depends on the class of print and the substance of the mount to which it is to be attached. For carbon prints to be attached to the thin vellum mounts so much in vogue at

the moment, the dry mounting method by shellac and hot pressure is practically the only satisfactory way. The use of fish glue applied to the extreme edges is very difficult, and can only be employed when one has become really expert, and is able to quickly apply just enough adhesive to cause adhesion, and not enough to exude. Platinotype prints are most quickly mounted if wetted, laid quickly between blotters, stacked face downwards on a clean sheet of glass and pasted. The paste is best applied by the finger, as a brush is liable to pick up the print or to disturb the pile of prints on the glass, one worker pasting and another lifting the print and laying it in position on the mount, to which it is pressed by means of a sheet of white blotting paper and a roller squeegee. The use of the finger in applying the paste ensures, by touch, that there shall be no gritty particles, and not too much paste.

Mounting Gelatine Prints.

Where the prints in question are P.O.P. or bromide—that is, prints with a gelatine surface—there is a twofold danger in the use of blotting-paper for pressing them to the mounts. First, the gelatine may adhere slightly to the blotting-paper and cause the print to leave the mount; and, second, the blotting-paper will be almost sure to leave some fluff on the surface of the print. For these prints the simplest method is to sponge them into contact with the mount. A very soft sponge, quite free from grittiness, is necessary. With margin mounts it is well to pass the damp sponge right over the margins, or a mark will remain where the moisture has dulled the surface of the board. One of the disadvantages of colour-stamped mounts is that this sponging cannot be done, as the moisture dissolves the colour used. Where the water is hard, markings will often occur on the surface of the print, the sponge leaving spots of water which dry up, leaving a minute deposit of lime. This once deposited on the print cannot be sponged off again, and it is most apparent on P.O.P. prints. The only way of avoiding these spots is to lay the print on one side after sponging down, and, in perhaps a minute, to remove all surface moisture with a piece of clean and not quite dry blotting-paper. The interval of a minute allows the adhesive to slightly bind print and mount together, especially at the edges, and there is then little or no danger of the blotting-paper lifting the print. For lifting the top print from the pad of prints when pasted, a small bone spatula is preferable to a pointed penknife, as it is less likely to increase the spotter's work by scratching the gelatine.

The Photographic Convention.

At its meeting last week the Council of the Photographic Convention elected to the presidency (in succession to Professor John Joly, F.R.S.) Mr. E. J. Humphery, who for many years has formed one of the Council, and has strongly identified himself with the activities of the Convention. The executive have reason to feel satisfied that the new president will spare himself in no direction where he can contribute to the success of the meeting to be held at Southampton in July next, and we ourselves are gratified in believing that those who would press upon the Council the desirability of the Convention taking a more serious view of its duties and responsibilities will be assured of support from the presidential chair. We must also make the announcement of a winter re-union of the Convention to be held at the galleries of the Royal Society of British Artists, Suffolk Street, Pall Mall, on Friday, January 12. The function will take the form of a reception, with vocal and instrumental music, and further particulars will shortly be available.

COPYING DAGUERRETYPE PICTURES.

In our issue of the 3rd ult. we dealt very fully with the method followed by the old Daguerreotypists in 'restoring,' or, in other words, cleaning faded, *i.e.*, tarnished Daguerreotype pictures. This tarnishing is generally brought about through the atmosphere, and the impurities it contains. More often than not it is caused by the Daguerreotype having been taken out of its case at some time or other for the purpose of being copied, and then put back again by an operator who has omitted to seal the sensitive silver plate from the air by the simple application of a paper binding. It is fortunate, however, that these pictures, unlike other photographs, can be restored to their original state by those familiar with the process.

It is seldom that a Daguerreotype is brought to a photographer to be restored without a request at the same time for copies or enlargements. Many look upon Daguerreotypes as being exceedingly difficult things to copy, that is, if one may judge from the number of queries that have, from time to time, been put to us, even by professional photographers, as to the best procedure. We have also read of some extraordinary devices, and arrangements, for the successful reproduction of these pictures; some of which must have amused those who have had any considerable experience in this class of work. As a matter of fact, a Daguerreotype picture is one of the easiest of all photographs to copy, if once the principle is understood, and, what is more, a reproduction from a good Daguerreotype, if properly made, more closely resembles a portrait from life than the copy of any other kind of photograph, as it is absolutely free from all texture, or grain. The difficulty—imaginary, be it said—in copying this class of picture is due to its highly reflective surface as in the case of all highly polished silver surfaces; but it should be borne in mind that the flat surface of the plate is very different from those, say, of vases and the like, which throw off reflections at all manner of angles. If we keep in mind that, in all cases, the angle of reflection is equal to the angle of incidence, the work is all plain sailing. We have simply to illuminate the picture at such an angle that the reflections from it are away from the camera, and not in its direction. If the picture be lighted at an angle—say of 45 deg.—the reflections from it will be at a similar angle, consequently quite away from the lens.

The most convenient place in which to copy a Daguerreotype is, perhaps, an ordinary room, the picture being placed at right angles to the window and close to it, so that it is illuminated by a strong side light only. Sunlight may be employed with excellent effect, provided the direct rays fall on the picture at, say, again, an angle of 45 deg. If an ordinary room be utilised, the camera being in an obscure light, there will be no reflection from the instrument, or from anything else that will give rise to trouble. If an ordinary room is not used, similar conditions should be observed in the studio—lighting the picture by a strong abrupt side light only, one as strong as possible. There need then be no trouble with reflections from surrounding objects. Now for the procedure.

The picture is taken out of its case and the covering glass removed; and we may here reiterate what was said in the previous article. The image is an exceedingly delicate one, and rests only on the surface of the metal plate, and is not held by a film of any kind, as in the case of a collodion or gelatine one. Therefore, the greatest care is necessary in handling it, as the slightest touch on the surface may leave a mark which nothing will afterwards remove. Any dust that may be on the picture should be blown off; a soft camel hair brush is sometimes

used, but it must be very lightly applied, and both it and the picture should be slightly warmed so as to avoid moisture, which might cause marks. Furthermore, a brush, if used, might injure the colouring, supposing the picture to be a coloured one. All Daguerreotypes, it may be mentioned, were coloured with dry powder colours, without any medium to bind them to the plate.

In fixing the picture to the copying board, it should be so arranged that the light falls on it parallel with the buffing marks, and not at right angles to them. The buffing, it may be explained, is the final polishing of the plate before it is sensitised, and its direction is readily recognised by all old Daguerreotypists. Sometimes this polishing was so perfect that the marks are not easily discernible, but it may generally be taken for granted that the final polishing was transversely across the plate, and

not longitudinally. This may necessitate the picture being placed somewhat diagonally on the copying board.

The lighting having been arranged as just directed, it only remains to take the negative in the ordinary way. Any plate and developer may be used, but over-exposure should be avoided, as that is conducive to flatness. The negative should be made tolerably vigorous, so that it yields brilliant prints. When the operation is concluded the picture should be at once sealed up to protect it from the air, as it was originally by the one who made it, and returned to its case. It should be recognised by all photographers who have Daguerreotypes to reproduce that, however good the copy may be, the original is always greatly valued by its possessor, and, therefore, every care should be taken to see that it is thoroughly protected from atmospheric influences before it is returned to the customer.

THE POSTAL CAMERA CLUB'S EXHIBITION AT THE R.P.S.

"Postal clubs are a very useful, but also a very unobtrusive, institution. Their influence is far-reaching in the photographic world, and yet nobody outside the photographic world has ever heard of them. Probably many photographers also are more or less unaware of their existence."

This pronouncement by Mr. J. C. Warburg, the hon. secretary of the Postal Camera Club, on the occasion of the opening of the house exhibition at the Royal Photographic Society on Friday last, indicates very clearly the present position of these clubs. The Postal Camera Club can, however, be regarded as the doyen of postal clubs, and the first institution of its kind to receive the honour of an invitation to provide an exhibition at the Royal Photographic Society.

When the constitution of the P.C.C. is examined this event is hardly to be wondered at when we find among the members the names of many of the foremost pictorial photographic workers of the day.

True, the membership is strictly limited to thirty, but this still further affords an indication of the quality of the work.

During his inaugural address on Friday, Mr. Warburg briefly sketched the career of the club and its present position.

The club was started in 1894 by the late Mr. FitzGerald Griffith, of County Clare, and Mr. W. R. Bland took over the secretaryship in 1895. It has been due to his devotion to its interests, and his unfailing tact and choice of new members that the club owes its present position. Many of the best-known names in the photographic world have figured in the list of members since that time, and as exigencies of business or other causes have made them relinquish their membership, new and equally well-known members have been found to take their places.

Mr. Warburg took over the honorary secretaryship in the early part of the present year, and the club is now as flourishing as at any time of its existence.

The method of circulation is the same as that adopted by nearly all similar institutions. Three or four portfolios follow one another with regularity in a settled order, so that each member receives one folio a month. Prints are inserted in "criticism sheets," on which the members express their opinions of the enclosed work, and after the prints have circulated twice they are removed by their respective owners, who have therefore to add a new one and remove an old one every month. In this way the members are treated to a sort of miniature circulating exhibition every month, and the benefit derived from the criticisms on their work by the other members, to say nothing of the ideas promulgated in an accompanying note-book, cannot

be over-estimated, even in the case of the most advanced workers. As the honorary secretary pointed out: "Criticism and the discussion and comparison of prints are of great value in keeping a man—or woman—fairly rational in their work. It does not check originality, but it keeps them from straying—not from the beaten track, but from straying into great extravagances. Although there may be many things in the present exhibition which will not be to everybody's taste, there is no doubt that all of them are serious efforts on the part of their authors to carry out their artistic ideas, and in considering them it is necessary to try to look upon them from the authors' standpoint."

"It is no good trying to make them fit a standard which they were never intended to fit. There is probably only one safe way of criticising or appraising the artistic value of a picture or other work of art, and that is, first, try to discover the author's intention and meaning, and then—having done so—to judge to what extent he has succeeded in carrying it out. But to decide whether an artist's ideals are worthy ones is a hazardous task. Before passing judgment on others, it will be well to make quite certain that our own taste and judgment are sufficiently cultured and refined to make us capable of such nice discrimination."

In the case of a circulating postal club, it is far easier to gauge a man's work rightly when it is seen monthly than when it is seen only at the yearly exhibitions.

Characteristic qualities can be distinguished from accidental ones, and it can be better seen what each member is striving for; what are his ideals, and in what way he seeks to attain them.

The visitor to the present show will, however, have a good opportunity of observing for himself the individual qualities of the different members in a very striking manner. In arranging the exhibition, the *cachet* of a portfolio club has been retained as much as possible. A few large pictures, too large for the portfolios, have, however, been included when they show a characteristic phase of the member's work, and also to give a little variety. Yet most of the pictures are such as have actually been in the portfolios, or may still be sent round. They have been arranged on the walls in panels or groups, and one of the first things that will inevitably strike the beholder is the obvious individuality displayed by each exhibitor. On no previous occasion has the subjugation of the camera to the individual taste of its user been more forcibly demonstrated than in this exhibition of the work of the P.C.C. Here we see the strength and richness of the work of W. R. Bland, and can compare it

with the delicacy and simplicity of Walter Benington's pictures of similar themes. The vigorous head studies of Lee Syms and the indefinable "gum" portraits by Page Croft call for similar comparison. Both have sought for different qualities and expressed them in a different way. Yet both have successfully carried out their ideas, and the results, when collected in groups, as in the present case, are eminently interesting.

The visitor will have occasion to admire the delicacy yet firmness of J. M. Whitehead's flower studies and his beautifully-restrained landscapes, and to wonder at the deliberation evinced in the productions of J. M. C. Grove. The clean, bright work of Arthur Marshall, and the heavier but equally impressive productions of James Gale and Hector Murchison, force comparison; while the predilection of J. C. Warburg for truth of tones and beauty of line and form is well evidenced in his contributions. The clever and amazingly strong poster designs and portrait work of Mrs. A. O. Jennings seem to belong to a different sphere altogether after contemplating the delicate and sunny figure studies of Miss Bessie Stanford. Yet both are delightful.

and each stamped with the individuality of their producers. Percy Lewis's dainty little Venetian scenes, teeming with light and breadth, in spite of their smallness, have obviously been produced by a different hand and understanding from F. J. Mortimer's pictures of storms at sea, although both are equally successful representations of water and atmospheric effect. The mystic figure studies of W. Stewart and those of Dr. F. Graves must again call attention to the influence of the man in the control of the camera; while the delicacy and variety of Miss A. Warburg's representations of familiar phases of our surroundings are in direct contrast to the bold, decisive productions of E. T. Holding.

The whole of the members of the club have responded to the invitation to exhibit, and no less than 160 pictures are on view. The show remains open at 66, Russell Square until the New Year, and admission is by production of visiting card.

Every photographer interested in the development of the pictorial side of his art should endeavour to see this exhibition of individualities.

PHOTOGRAPHY THE SERVANT OF SCIENCE.

II.

Reducers and Intensifiers.

The negative at this stage is generally finished, but circumstances may be such that the image is too dense or not dense enough for convenient working with. If any quantitative value at all is placed on the gradation, and personally I should say in all cases, the image should not be reduced, for there is no reducing agent that is to be depended on. There are many ways of thinning the image, but none that can be depended on to act proportionately. The persulphates and one or two other substances do approximate to a proportional action, but why they should, how they act, and what the remaining image consists of, are not known. Therefore, for scientific purposes, and indeed for all valuable negatives, there is no reducer available. The reason, of course, is clear—it is the necessarily incomplete action of the reagent, for a complete action would remove the image entirely. In an incomplete change it is natural that the thinner parts should be affected to a greater proportion than the denser, as the bulk of the particles in the thinner deposits lie nearer the surface and so are more easily reached by a solution applied to the surface.

Intensification.

But if the image is not dense enough, it is easy to increase its density in a strictly proportional manner by taking care to change every particle of silver in exactly the same way. In intensification it is of the utmost importance that every change be thorough, and of such a character that no other change sets in when prolonging the action of any reagent used. The increase of density as so produced must not be too great and the resulting image should not be coloured, it should be indistinguishable from the original in appearance except as regards opacity, and equally permanent. The application of mercuric chloride followed by ferrous oxalate fulfils these conditions; it is the only method I know of that does, and also has the advantage that the intensified negative may be regarded as if not intensified so far as any photographic process is concerned. Chemically, this method is perfectly definite, each atom of metal, whether of silver or mercury, has an atom of mercury added to it. And the change in opacity is also definite, for the opacity logarithm is in all cases multiplied by 1.45.

Development and Intensification.

The relationship between development and intensification is important and has been the subject of a good deal of investigation. We have often been told that intensification gives the same result as continued development. Of course we must sup-

pose that there is sufficient exposure effect to make continued development possible, though this primary necessity is not always specified, and indeed is often absent. Now I fearlessly assert that optical methods alone are not sufficient to settle such matters as these. It is necessary also to investigate the chemical changes that take place, and the conditions under which they take place, and then to consider the whole of the evidence available. The fact that this statement of similarity was first made as if all methods of intensification were alike in effect and *proved* by experiment with a method whose chief characteristic is its uncertainty, and almost invariable departure from the stated rule, may perhaps be accepted as evidence in favour of the insufficiency of optical methods. But if we take the mercury and ferrous oxalate method which does give strictly proportional results, this rule as to the similarity of intensification and continued development does not hold good. I grant that it may, and in some cases probably does, or at least it comes so near to following this fictitious rule that it would be quibbling to deny it. But this goes to show how insufficient much of the evidence is that has been accepted by some investigators as fit foundation for theories and laws. I disputed this matter with Dr. Hurter a good many years ago, because it is so clear that you cannot intensify an image that you have not got, and that if development is stopped before the image is fully out, intensification cannot complete the development. Dr. Hurter said that the image is there, although you cannot see it, a supposition necessary to the idea under discussion, but in this he was in error. Anyone can prove that it is as I say, without any measurement of the results, just as surely as one can prove that a half-hundredweight is heavier than a pound weight without ascertaining the exact weight of either. Sometimes the very striving after exactness fogs or hinders one's powers of observation, as the individual soldier, busy with his personal fighting, cannot tell whether the battle is being lost or won. I have emphasised this, not only because of its intrinsic importance, but because we have had far too much generalisation from quite insufficient evidence, particularly of late years.

Some developers give all the detail almost simultaneously; in such cases further development and suitable intensification do seem to give similar results, always provided that there is enough exposure effect to render continued development possible. Other developers give the image gradually; in such cases it is quite certain that continued development and intensification do not produce similar results. It has been replied that:

the difference is only in the under-exposed parts which are relatively unimportant, to which I should answer that even granting for the moment that it is so, and it has never been proved, the under-exposed parts may be the only important parts. Still it is not a question of importance but of fact.

There is but little time left to speak of methods of measurement and of printing processes. If you want to measure a thing, then I would say measure it, and do not be content with measuring a part of it, especially an uncertain and variable part. If you want to measure opacity by estimating the light transmitted, it is not safe to neglect the scattered light, as many do, deceiving oneself with the idea that the light scattered is a constant proportion of the whole. A negative is not homogeneous, and apparatus and methods that are quite satisfactory for homogeneous substances are not, therefore, suitable for the measurement of negatives. The Abney screen is an ingenious and excellent device that overcomes this

difficulty. Other methods, I know, have a greater semblance of exactness, but what is the use of this with an ever-present and variable error?

As to printing, I think that the best advice that can be given to a scientific worker is to avoid it as much as possible. In a print the errors of the printing process are added to those of the negative—inherent as well as accidental errors. The possible range of luminosities is smaller in the print than the negative, therefore in printing there is almost always loss. But not always, for printing papers are now made that will give a brilliant print from a poor thin negative, and brilliance is the photographic expression for clear detail.

And now I feel that, while perhaps over-straining your patience, I have treated many points too superficially or too obscurely, but I ask you to forget my faults in the study of the subject, and to accept my thanks for your kind attention.

CHAPMAN JONES.

THE WEEK IN HISTORY.

DECEMBER the fifth, 1829, is quite one of the red-letter days of photography, for it was on that date that Daguerre signed the receipt for the document in which Niépce described to him the process which he himself called "Heliographie," and which Daguerre perfected and altered, until ten years later it became the process which bore his own name. The labour of Niépce was thus confided to Daguerre in accordance with the terms of the deed of partnership between them, which was signed on the fourteenth of December, 1829. The description was called by Niépce a "Notice sur l'Heliographie," and first appeared some years after his death, when Daguerre inserted it in his "Historique et Description des Procédés du Daguerrotype et du Diorama," adding a number of sharp notes to statements of Niépce which he considered incorrect, and emphasising points which proved the distinctiveness of his own process from that of M. Niépce. A few extracts from this paper must be made, since it embodies all that is known of Niépce's work from first to last. True, we have his letters to his brother, but the "Notice" is the only coherent account of the researches:—

"The discovery, which I have made and to which I give the name *Heliography*, consists in the reproduction, spontaneously by the action of light, in gradations ranging from black to white,¹ of the images produced by the camera obscura.

Fundamental Principle of the Discovery.

"Light, in its states of composition and decomposition, acts chemically on many substances; it is absorbed, it combines with them and gives them new properties. Thus it increases the viscosity of some bodies, even solidifying them, and makes them more or less insoluble, according to the length and intensity of its action. Such is, in brief, the theory of the discovery.

The Material Used.—Preparation.

"The substance which I use and with which I have secured the best results is *asphaltum* or *Bitumen of Judæa*, prepared as follows:—

"I half fill a glass with the powdered bitumen and pour over it, drop by drop, essential oil of lavender until the bitumen no longer absorbs it, and is thoroughly saturated with it. I then add enough of the essential oil to cover the mixture to the depth of about three lines, after which the whole must be covered up and left, at a gentle heat, until the essence is saturated with the colouring matter of the bitumen. If this varnish is not then thick enough, I leave it to evaporate in the open air in a dish, protecting it from damp which alters and finally decomposes it. This is particularly noticeable in the present cold, wet weather.²

"A small quantity of this varnish applied cold, with a tuft

of very soft leather, to a highly polished silver plate gives a thin and very uniform film of a bright red colour.³ The plate is next placed on a warm plate covered with a double thickness of paper (previously dried), and as soon as the varnish has lost all stickiness, the plate is removed to cool, and the drying finished, at a very moderate temperature, out of contact with moist air. I must not forget to observe that this precaution is very necessary. A light disc, to the centre of which a short handle is attached, held to the mouth, is used to arrest and condense one's breath.

"The plate, prepared in this way, can be at once exposed to the action of light; but even after it has been exposed for a time long enough to allow the action to take place, no visible result is obtained.⁴ The impression is latent, and, in order to render it apparent, a solvent has to be used.

The Solvent.—Method of Preparation.

"It is difficult to state the exact composition of the solvent, as it must be altered according to the result which is desired. But, other things being equal, it is better to have it too weak than too strong.⁵ I prefer to use one part (volume, not weight) of essential oil of lavender to six parts of white petroleum oil. The mixture is milky at first, but becomes perfectly clear at the end of two or three days. It can be used several times over, losing its solvent properties only when it becomes nearly saturated. When it becomes opaque and dark in colour it can then be distilled, and is made ready for use again.

"The varnished plate, having been withdrawn from the camera obscura, a sufficient quantity of this solvent is poured into an iron dish, about an inch longer and wider than the plate, to completely cover the plate. The latter is then placed in the liquid, and by looking at it at a certain angle the image is seen to appear and to gradually develop, although still veiled by the oil above it, which is more or less saturated with varnish. The plate is then removed and placed in a vertical position in order to let the solvent drain off. When it no longer escapes, the last operation—and by no means the least in importance—is proceeded with.

Application of Heliographic Processes.

"The varnish employed being applicable to stone, metal, or glass, without in any way altering the process. I will speak only of its application to silver plate or glass, remarking, however,

(¹) Note by Daguerre:—It is impossible, by such a method, to obtain a film so uniform as to give in the camera the fineness which the modifications of light require.

(²) Note by Daguerre:—If the image were completely invisible there would be no result. A faint image is necessary to obtain a successful print.

(³) Note by Daguerre:—Both these give rise to certain inconveniences. In the first, the image does not develop sufficiently; in the second, it is completely removed.

(¹) Note by M. Daguerre:—The purest light given by this process is not white.

(²) Note by M. Daguerre:—This note was written in December.

in reference to its use for engraving on copper, that a little wax dissolved in oil of lavender may be added to the varnish.⁶

"Up to the present a silver plate, from its white colour and brightness, after washing, provided that the picture has been dried, a very fair result is obtained. But it would be better, if by blackening the silver plate, the various gradations of light and shade could be represented. I, therefore, devoted my attention to this question, using, at first, liquid sulphide of potassium. But this reagent attacks the varnish when concentrated, and only reddens the metal, when dilute, so that I have abandoned its use, and now use iodine with the prospect of better success, which is easily vaporised at the ordinary temperature."⁷

"In order to blacken a plate by this process it is only necessary to place it against one of the sides of a box open above, placing a few fragments of iodine in a small groove made on the opposite side at the bottom of the box. The top of the box is

(⁶) Note by M. Daguerre:—It may be noted that the engraving of which M. Niépce speaks was always made on a sensitised plate exposed in contact with a print, and that the use of the wax to which he refers would have neutralised the effect of the decomposition of the bitumen in the camera where the light is very weak; the presence of the wax did not, however, interfere with the copying of engravings, which he exposed for three or four hours to direct sunlight.

(⁷) Note by M. Daguerre:—It is important to note the use of iodine thus made by M. Niépce for blackening his plates proves that he was not aware of the property which this substance possesses, when brought into contact with silver, of undergoing decomposition in light; on the contrary, he gives it here as a method of fixing his prints.

covered with a piece of glass through which the change, which takes place slowly but steadily, can be watched. The varnish can afterwards be removed with alcohol, leaving no trace of the first part of the process. As this method is quite new to me I will only mention this simple plan until further experiment shall have enabled me to give a more detailed description.

"In reference to the method of applying the varnish, I must repeat that it must be used of only such consistency as to form a film, compact, but as thin as possible; it, thus, best resists the action of the solvent and is more sensitive to light.

"As regards using iodine for blackening, as also when using acid for engraving on copper, it is necessary that the varnish, after washing, shall be as described in the second experiment on glass, above quoted, for it is then least penetrable by iodine or by acids,⁸ principally in the parts where it has retained its transparency, and it is only in this way that success can be expected even with the most perfect optical appliances."⁹

HISTORICUS.

(⁸) Note by M. Daguerre:—The print which was the origin of this statement was exposed to light in the camera, and although M. Niépce refers here to iodine for blackening and acid for etching, copper being presumably meant, these two operations would have given no gradation of tones. As a matter of fact, the image was obtained by the greater or lesser thicknesses of varnish corresponding to the action of light on the film, and it is impossible for the acid to act in this way, neither did M. Niépce ever make an engraved plate by direct exposures in the camera.

(⁹) Note by M. Daguerre:—The best optical apparatus cannot alter the fact noted above.

COLOUR PHOTOGRAPHY ON PAPER.

[For the following itemised report of a paper by the Rev. Johnson Barker before the Worcestershire Camera Club and Photographic Survey Society on Wednesday in last week we are indebted to the Honorary Secretary, Mr. W. W. Harris. The process worked by Mr. Barker consists in superimposing yellow and red images on a ferro-prussiate base, with precautions which are detailed in the description which follows.]

Colours for Home-made Filters.

For the preparation of the negatives it was found most convenient to use the filter in front of the lens. For all practical purposes of an inexpensive process the lecturer stated that lantern plates, fixed and stained, could be recommended. He stained two plates, and bound them together in the form of an ordinary lantern slide, securing optical contact between the two with Canada balsam. A number of colours were mentioned, but, taking the three primary colours, the following were found suitable, viz:—

For red—fast scarlet for wool.

For blue—fast light blue for wool.

For yellow—fast yellow for cotton; besides which three, a useful colour is:—

For green—fast green for wool.

"Diamond" dyes of these colours are used, and are chosen because easily obtainable and cheap. The stains commonly recommended and employed are expensive, and generally require to be specially ordered. Do not use strong solutions in staining the plates. More even results are obtained with dilution and longer immersion. Afterwards, thoroughly rinse until there is only a slight discharge of colour, and allow to dry spontaneously. Test exposures should now be made, with and without screens, which can be made on one plate by using strips of opaque paper or shields; a proper comparison of these exposures will give the relative exposures required for each screen. After obtaining the three negatives through the colour screens, the next consideration will be the coating of the papers.

Making the Three-colour Print.

We commence by making the first on the ferro-prussiate paper, as this is not successful upon the bichromated red and yellow applica-

tions. To obtain vigorous and brilliant prints the paper is best freshly sensitised, using:—

A.—Ferric ammonium citrate	1 oz.
Water	6 oz.
B.—Potass ferriocyanide	1 oz.
Water	10 oz.

For use, mix equal parts and filter; coat the paper in the usual manner, and pin up to dry. Next procure twopenny tubes of moist colours, yellow and red, a bottle of ordinary office gum, and a 1-in. camel-hair flat brush. Take equal proportions of a 10 per cent. solution of bichromate of potassium, and mix thoroughly with sufficient yellow pigment to form a wash of about the consistency of milk, coating with this the surface of the dried blue print. Care should be taken to use the brush lightly in all directions to secure even distribution of the colour, which should be of no deeper density than the deepest shadow in the resulting print. Make the exposure through the second negative in the usual manner, and carry to a point when the image can be fairly seen. Then float the print, face downwards, in cold water, and let development proceed of itself. Afterwards, thoroughly dry and proceed in the same manner as before, by sensitising for the red, drying, printing, and developing just the same. The operation of colour sensitising may be carried on in daylight or gaslight, as the paper only becomes sensitive when dry.

Correct registration must be made in the successive printings, and can be secured in several ways. It is not a difficult matter to do this by holding up the printing frame to the light, and thus set the print in register with each successive negative.

Points to be Noted.

Allow each print to dry spontaneously and thoroughly before applying the next coating.

Although other forms of pigment may be used, the tubes of moist colours will be found to work most freely and evenly.

A good quality cartridge paper will be found suitable, but this must be quite free from water marks, and it is advisable first of all to thoroughly soak and dry the paper, or trouble will ensue from shrinkage, and thus prevent exact register. Practically there is no limit to the colours which may be used, but in this initial stage gamboge and crimson lake may be tried. It should be noted that the order of colours is not according to the usual rule, but in this process must be followed as given.

Some Results.

Not the least interesting part of the demonstration was the showing of a selection of Mr. Johnson Barker's three-colour prints, on which one or two of the members present found it hard to believe that brush work had not been used. The prints possessed a charm of softness and blend of colour pleasing in the extreme, and were inspected by the members with a great amount of interest and surprise at their beauty of colour rendering. Some slides by the Sanger Shepherd process were also shown.

"THE BRITISH JOURNAL ALMANAC, 1906."

This day (Friday) photographers throughout the United Kingdom will be able to obtain the 1906 volume of "The British Journal Photographic Almanac." The features and contents of the "Almanac" have been kept prominently before our readers during the past few weeks with the object of emphasising to every intending purchaser the fact that an order in advance should be given if it is desired to make certain of procuring a copy. In some respects, too, the "Almanac" differs from its recent predecessors, and now that the issue is in the hands of the dealers and booksellers up and down the country, we may, on behalf of the publishers, once more outline the general nature and arrangement of the contents.

The 1906 "Almanac" includes:—

A directory of photographic societies in the United Kingdom and Colonies, compiled from official returns, and giving, among other particulars, the place and time of meeting. (P. 584.)

Full particulars of important photographic bodies, such as The Royal Photographic Society, the Professional Photographers' Association, the Photographic Convention, the Linked Ring, etc. (P. 615.)

A complete treatise, in popular language on "Photographic Copyright," from the pen of the Editor. It deals with the rights, responsibilities, and liabilities of photographers in their dealing with sitters and with the Press. (P. 657.)

Contributed articles by leading writers. (P. 884.)

Epitome of progress—a systematic and classified review of progress in every branch of photography, arranged under the following

headings:—APPARATUS AND EQUIPMENT; PHOTOGRAPHING VARIOUS SUBJECTS; NEGATIVE PROCESSES; PRINTING PROCESSES; COLOUR PHOTOGRAPHY; GENERAL. (P. 721.)

Recent novelties in apparatus. (Pp. 629 and 875.)

Formulae for the principal photographic processes, entirely revised and made representative of the latest approved practice. (P. 941.)

Working formulae for the use of the principal plates and papers on the market, revised to date. (P. 991.)

Miscellaneous information on copyright, poisons, patents, etc. (P. 1064.)

Tables of weights and measures, solubilities, exposure, lens calculations, etc., revised and rearranged throughout. (P. 1081.)

The whole of this large and varied mass of information is made accessible by the provision of:—(1) A contents on page 651, showing where any given item must be sought; and (2) An index of items (p. 1127), leading the consultant to the paragraph he requires.

The only task—and that a particularly unwelcome one—remaining to the Editor is to express his regret that exigency of space has compelled him to hold out of the volume several contributions which are printed below. In taking this course the Editor would bring to the knowledge of the contributors the fact that their communications were not withdrawn until a considerable reduction of editorial matter had proved insufficient to prevent the volume from exceeding limits which, as those experienced in book production are aware, are laid upon editor and publisher.

A GOOD FORM OF DEVELOPING POWDER.

By W. H. WALMSLEY.

A dozen or more years ago I sent to the ALMANAC a short communication on the advantages of a developer that might be kept in powdered form for an indefinite period, always ready for use by simply dissolving in water, and entirely free from deterioration that all solutions—save Rodinal alone—are invariably subject to. The reagents as given in the little paper were eikonogen and hydroquinone (now so well known) in a mixed form, which I had then used since their introduction in the early eighties. During the years that have elapsed since that article was written I have used all—or nearly all—of the rapidly increasing family of developing reagents, and, it must be said, with excellent results in each case. But I found myself ever returning to the old "Eiko-Hydro" combination after straying awhile in other fields, finding it like an old and tried friend—always dependable. It is not the purpose of this present writing to extol the virtues of any developing reagent, but to jot down the method of keeping this one in a fixed, dry state, unchanging and ever ready for use, together with the simple mode of so doing that I have found convenient and practical.

Two powders are required, both in the form of mixtures—hydroquinone and eikonogen forming the one, the alkali preservative the other. These may, of course, be compounded in any desired quantities. For the amateur, in whose interests these lines are mainly written, I would suggest 2 ozs. as being a convenient quantity to prepare at one time, and screw-cap glass jars, such as commercial photo-mountant comes in, as being very excellent containers. After exhaustive experiments the following proportions of each reagent and salt forming the

powders were found to be the best and practically perfect, so that I have made no change in them during many years:—

No. 1. Eikonogen	400 grs.
Hydroquinone	320 "
Mix very thoroughly, and put into one of the jars.					
No. 2. Sodium sulphite— <i>dried and powdered</i>	960 "
Lithium carbonate	240 "
Also mix thoroughly and put into the second jar.					

Thus prepared, the powders are always ready to make up the fluid developer *at once*, and, as stated, they keep indefinitely. I have noticed no change in them after being mixed more than a year. Of course, they were kept in the screw-top jars, which, having a cork lining to the cover, preserved the contents from the outside air.

For all makes of plates with which I am acquainted, and for anywhere near correct exposures, the developer may be compounded as follows, from which I never find it necessary to vary:—

Water	4 ozs.
No. 1...	25 grs.
No. 2	15 "

Dissolve in order named, stirring with a glass rod; the chemicals will dissolve very quickly. To avoid the trouble of weighing each time, a couple of little dippers, that will hold just the right quantity when filled, may be used. I have found small thimbles very excellent for the purpose. A stiff tin handle can be soldered to each for convenience, and when nickel-plated they are very neat and nice-looking, as well as useful.

We have thus but $3\frac{3}{4}$ grs. of the eiko-hydro mixture to each ounce of developer, and about $1\frac{1}{2}$ grs. of the alkali to the same volume, making it one of the cheapest developers that has ever come under my observation—perhaps the very cheapest, notwithstanding the high price of lithium carbonate. The small quantity of it that is used, compared with the much larger amount necessary with sodium carbonate, is a prime factor in lessening its first cost, whilst the resultant negatives are softer and in every way better than those developed with sodium carbonate as the alkali. Any desired amount of density may be obtained, there is never any tendency to fog, the development is not too prolonged, and the negative a thing of beauty in itself. For photo-micrographic work I know no method of development equal to it.

IRON IN PLATINUM PRINTS.

By J. H. BALDOCK, F.R.P.S., F.C.S.

Some unexpected results on platinum prints having lately been brought to my notice, which I thought could only be produced owing to the presence of iron in the paper, I determined to once again examine this point. Some readers may remember a paper by Mr. Chapman Jones in the "Journal of the Royal Photographic Society," May 30, 1895; and one by myself in "The British Journal of Photography," November 8, of the same year.

The question has been raised whether citric acid (a vegetable acid) is not better to use than hydrochloric acid (a mineral acid) for the elimination of iron from a platinum print. My procedure, therefore, was as follows:—I made a solution of pure hydrochloric acid $\frac{1}{2}$ oz. to a pint of distilled water, and one of citric acid 1 oz. to a pint; then, having placed a half plate piece of platinum paper (not a print) in two separate dishes, the acid solutions were poured over them, and allowed to stand for 10 minutes; these were drained off, and the process repeated a second time for 15 minutes, and a third time for 20 minutes, such times being largely in excess of the time usually given.

The papers were then well washed in distilled water and dried. They were then burnt to a white ash in two separate platinum crucibles, the ash was boiled in perfectly pure hydrochloric acid, filtered, rendered alkaline with ammonia, and ammonium sulphide added. This gave a precipitate of a greenish black colour, much more copious in the case of citric acid; the precipitates were separately dissolved in aqua-regia, diluted, filtered, and again rendered alkaline with ammonia; a brown precipitate was now obtained on the filter, more copious again in the case of citric acid. This was dissolved in a few drops of the pure hydrochloric acid, filtered, and just neutralised with ammonia; this final solution was then further tested for iron in the usual way, positive results being obtained in both cases. Although possibly the citric acid may not have such a softening effect on the paper as hydrochloric acid, a point of no great importance. Yet from the above experiments it does not seem to be so efficacious for the removal of the iron as does hydrochloric acid.

It would thus appear that working under commercial conditions, where several prints have to be in the baths at one time, and no very great length of time allowed, it is practically impossible that all the iron can be removed. The prints nevertheless, show perfectly pure whites, and under ordinary conditions, do not seem to be any the worse; yet, under certain circumstances, the presence of the iron may make itself uncomfortably felt.

Trying if all the iron could be removed I took another half plate piece of the paper, and kept it for 48 hours in the bath of perfectly pure hydrochloric acid $\frac{1}{2}$ oz. to the pint of pure distilled water, changing the bath at frequent intervals, washing, drying, calcining, etc., as before, with the result that practically the whole of the iron was removed and unweighable, an almost invisible quantity remaining at the end of the operations. Of course, as several filter papers have to be used, it is quite necessary that these, as well as all the chemicals employed, should be pure and free from iron.

THE TRIPOD AS A STUDIO STAND.

By J. McINTOSH.

Everyone who has attempted to take portraits indoors or out of doors, but particularly the former, with no better support for the camera than a tripod, will bless the unknown genius who invented the little piece of apparatus which I am about to describe. We all

know the difficulties that are met with when working in an ordinary room in getting the image the right size, in getting the figure in the right place on the focussing screen, and in keeping what should be upright lines truly vertical. The slightest alteration in the camera necessitates a readjustment of the tripod, with the result that photographer and sitter are both worn out before the exposure is made.

A few months back, when rummaging through some of the "variorums" in a lumber room at 66, Russell Square, I came across a curious piece of apparatus which when unfolded presented the appearance seen in the accompanying sketch. It is, in fact, a movable

support for the tripod, the points of which are placed in the holes marked A, B, and C. Once the camera has been raised to the correct weight and properly levelled, it and the tripod may be wheeled about to any position with the greatest of ease.

The sketch almost explains the contrivance without further description, but to make everything clear it may be said that the central piece is a triangle of about 9 in. on each side. Underneath is another triangle, with all three points cut off so as to form a hexagon of about 3 in. on each face. Three arms are then attached on the under side by "backflap" hinges. The arms may be of any convenient length, and at the extremity of each a castor is fastened.

When in use the contrivance is rigid, as the pressure, being downward, locks the hinged parts together. When not in use the arms fold downward and the contrivance may be stored away in little space. In conclusion, I desire to offer my congratulations to the unknown inventor.

ASTRONOMICAL PHOTOGRAPHY.

By J. W. SALISBURY.

A photograph of the sun may be taken in bright summer light, in about one-fiftieth of a second, with an aperture of $f/64$; use a very slow plate with a fine grain, such as a lantern plate, and a very dilute developer (not pyro, as liability to stain is feared, owing to the prolonged development).

When photographing the moon, an exposure of one-quarter of a second at $f/5.6$, soon after she has reached her first quarter, will give a good negative, using a very rapid plate. Owing to the rapidity of the moon's motion, exposures, with stationary apparatus, should not exceed one-quarter of a second from small images, and for larger, shorter exposures still will be required in order to avoid the blurring caused by the displacement of the image on the plate.

If driving mechanism is used, longer exposures can of course be given, and consequently larger photographs obtained, but there is always a limit to the magnification, as, after a certain point, further magnification will not resolve any more detail.

Let p = the principal focus of the object glass.

a = the diameter of the object glass.

l = the wave length of the light used to illuminate the object.

c = the diameter of the greatest disc of confusion permissible.

Then cp/al will be the greatest effective magnification that can be used, and greater magnification will only increase the size of the image without revealing any more detail, and will to an extent destroy the detail in the fainter parts of the image.

For photographing we may take $l = 0.00073$, giving a limit of 1360 p/a diameters of magnification for maximum detail. We have taken $c = 1/100$ inch.

For visual purposes a magnification of 770 p/a will resolve the maximum detail a keen eye can perceive.

Since most telescopes have a focus of fourteen times the diameter of the object glass approximately, the useful magnifica-

tion will not exceed 100 diameters per inch in diameter of the object glass for photographic purposes, and 55 diameters for visual purposes.

If extreme magnification is not required, the clearest view will probably be obtained with a magnification of 35 diameters per inch of aperture.

HOW THE DENSITY RATIOS ARE ALTERED.

By H. J. CHANNON.

The year 1890 marked a most important stage in the progress of photography, and a very advantageous new start was then made towards placing it upon a true scientific basis. The paper by Messrs. Hurter and Driffield of that year, which has done so much to give life and interest to the scientific side of photography, being, however, a new departure in the line of investigation pursued, it was naturally to be expected that the conclusions arrived at in it would not all be absolutely sound, especially as there is internal evidence that the authors were not very well acquainted with previous photographic literature. Consequently, as was to be anticipated, first conclusions in some cases have had to be much modified, and this is especially so in the matter of development, where further investigations by Messrs. Hurter and Driffield themselves, and by other experimenters, have shown the necessity.

But a remarkable feature in this history is that their thick and thin supporters seem quite unaware of that fact, and continue to denounce all who question any of the opinions expressed in the paper of 1890 as merely fossil remains of the wet plate age, who are incapable of appreciating new ideas. At a meeting of the Society of Arts, in February, for instance, some innocent fun was provided for the amusement of the audience at the expense of those middle-headed persons who had criticised unfavourably the doctrine of the absolute unalterability of the density ratios. Unfortunately, the fact was overlooked that time had proved those critics to have been entirely in the right. The ratios are so far alterable, in fact, all the investigations of recent years go to show that over-exposure is to a great extent curable by our at present available methods, and the faults arising from under-exposure may possibly be abated.

The following are well established facts:—In the presence of a soluble bromide, the density ratios change continually during development, hence the plate has always *different speeds* at each stage, and, by choosing the correct length of development, we may suit the gradation to the exposure. Of course, if density is then deficient, the plate must be intensified. If the plate itself contains a soluble bromide, this variation in inertia will occur in spite of us, and the time of development must then necessarily be adapted to suit the gradation required. Mr. Mees recently mentioned a case in which the speed varied from 150 Watkins to 1000, according to the time of development. Messrs. Mees and Sheppard have shown ("Phot. Journ.," Vol. XLIV. p. 286) that considerable differences in speed are found in some plates, but not all, when developed by different reducing agents. Many workers, too, claim that greatly increased restraining power may be gained by using citrates in place of bromides; that matter, I think, has not been scientifically investigated. But, in fact, to be convinced that a very great amount of control over the gradations can be had, it is only necessary to glance at Mr. H. W. Bennett's diagram 16, given in his paper read before the Royal Photographic Society on March 10, 1903.

It is clear, then, that a photographer has great resources if it be required to remedy known errors of exposure, and it is difficult to see why strong objections should be raised, as in some quarters they are, to his employing such means as are best adapted to the purpose. I entirely agree with the opinion that the best general system of work is to use all available means to obtain correct exposure, and then, that being secured, to develop by a good scientific mechanical method; but few photographers can avoid cases where incorrect exposure must be given, and then I think it wiser to take advantage of all the benefit that modified development can give, rather than sacrifice the qualities of a negative for the sake of remaining slaves to a mechanical routine.

NOTES ON THE USE OF LENSES.

By J. LEISK.

However much skill, ingenuity, and labour may have been expended on the production of a modern camera, it will be admitted that the most important factor of any camera is the lens.

Given a good lens, in skilful hands, good work may be turned out with otherwise very ordinary apparatus, provided it be light-tight; but, on the other hand, if the lens be faulty or unsuitable for the subject, all the "latest improvements" and superior workmanship will not improve matters to any extent.

The special optical qualities of modern lenses are distinguished by such terms as *aplanat*, *stigmatic*, *anastigmatic*, *holostigmatic*, *euryscope*, etc., etc., and, of course, every makers' lenses are *the best*, though, parenthetically, I may remark, that in my experience the higher-priced lenses are not necessarily the best, but as it is not my intention to discuss the optical qualities of such lenses, it is sufficient to indicate the practical test, which is that the lens should cover the whole of the plate, for which it is made, sharply without undue stopping down, and also bring the foreground, say, 20 yards distant, and the more distant objects into good, sharp focus.

Now, suppose a beginner in photography has acquired a quarter-plate camera, fitted with a good, rapid rectilinear lens of the quality indicated, he will naturally wish to follow the prevailing fashion, and take views for picture-postcards, for which his quarter-plate is too small, as is also a 5x4 camera; hence, he must invest in a half-plate camera, and if money is no object he will get it fitted with an expensive R.R. lens complete, but when he begins to use it he will find that though the scale is larger, the half-plate will take in little, if any, more extent of view than did his quarter-plate, the reason being that each lens is constructed so as to include about the same angle or *extent of view* on their respective plates, but as the quarter-plate lens will have a focal length of between 5 and 6 inches, while the focal length of the other will be between 9 and 10 inches, it follows that the quarter-plate lens, as compared with the half-plate one, is a *wide angle* lens and will include a much wider extent of view when used on a half-plate than the ordinary half-plate lens, or, in other words, the difference between a "wide angle" lens and a "narrow angle" lens is that the former is of shorter focus than the latter. Hence, a good R.R. quarter-plate lens may be fitted to a half-plate camera, by the use of an adaptor or extra sliding front, and used when it is necessary to extend the angle of view, and if the lens be a really good one, the back lens of the combination may be used as a single or landscape half-plate lens, and thus save the expense of two lenses when investing in a half-plate camera.

Of course, there are specially constructed "wide angle" lenses on the market which are supposed to cover the plate sharp with a larger stop than those I have indicated; but the question comes to be: are the advantages worth the extra expense to the possessor of a good quarter-plate lens? In my own experience it is not, seeing that I have a quarter-plate R.R. lens that can cover a half-plate sharp enough for all ordinary purposes, and as the speed of a lens is regulated by the proportion between the size of stop and *focal length*, and not by the *size of the plate*, I find it rapid enough for instantaneous exposures.

In photographing buildings, streets, etc., when space is often limited and it is impossible to go further back, a wide angle lens is a necessity in order to secure the whole subject on the plate; but for all other outdoor subjects a 9-inch focus has a tendency to dwarf in appearance the more distant objects, and to produce "violent" perspective of the very near objects—the shorter the focus of the lens the more violent will the perspective be, and here comes in a very curious optical effect. If we take a street view with, say, a 3-inch focus lens, the perspective will be *very violent*, the nearer houses appearing large out of proportion to those a short distance away, but if we examine the print through a 3-inch focus lens the distortion will disappear and the lines of the view appear quite correct, the explanation being that a person with normal sight cannot view the picture so near the eyes as the focal length of the lens by which it was taken—viz., 3 inches—without the intervention of a lens of that focus, but by the aid of such a lens the lines of the picture are refracted to the normal, and so reach the retina of the eye.

The moral, or lesson, we learn from this, is that the lens whose focal length is nearest to the distance we hold a book from our eyes when reading, is the one that will most truly render natural objects near and distant *as we see them*, otherwise if taken with a shorter focus lens they will appear more natural and pleasing if seen through a lens or eyeglass of the same focal length as that of the camera by which they were taken.

When stereoscopic pictures are viewed through lenses or prisms of the same focal lengths as the lens of the camera by which they were taken, in addition to the solid appearance of the objects caused by the binocular arrangement, one loses the sense of looking at a *small picture*, the object assumes a natural or life size, and one is able to judge distances in the picture almost as accurately as if the actual scene was before him.

THE NATURE OF THE LATENT IMAGE.

I.

(Abstract of a paper read by Dr. Eder before the Viennese Academy of Sciences.)

THE nature of the latent image on the haloids of silver is, despite numerous investigations, not determined. The so-called subhaloid theory, which was first advanced fifty years ago, and has been repeatedly disputed, is the most probable. This assumes that silver bromide AgBr , loses a very small quantity (y) of bromide, so that one, or as the author assumes, several kinds of silver subbromide, $\text{Ag}_x \text{Br}_{x-y}$, of unknown atomic composition are formed. Luther supports the formation of one subhaloid Ag_2Br or Ag_3Cl , and considers that the image obtained by printing out contains more or less of this substance; he does not think that it is probable that there is a solid solution between the AgBr and Ag_2Br , whilst Carey Lea, Bauer, and Gunther support this view, and that with increasing exposure black products are continuously formed.

All these theories assume the formation of the subhaloid during exposure, but the evolution of bromine is so small that it evades detection. In opposition to the subhaloid theory is that which assumes that the haloids are reduced to metallic silver, a view first expressed by Arago, and more recently by Abegg in his silver-grain theory; but this is not now of much moment, as it cannot satisfactorily explain the phenomena of development.

Another theory, the structure theory, assumes that there is no photochemical evolution of bromine in the silver bromide molecule, but that a molecular change takes place, that is a splitting up of the complex AgBr molecule group into a simple one.

Guntz has recently advanced the view that the latent image (on silver chloride) is a physical modification, but that there is no chemical dissociation by the light; and he considers that there is only an evolution of the haloid and formation of the silver subhaloid, when there is direct blackening; this, the subchloride or half-chloride, is stable to nitric acid in the dark, but not in light, and is decomposed by fixing agents with the precipitation of metallic silver and the formation of the soluble haloid.

Lüppo-Cramer advanced the theory that the latent image consisted of two substances, the lesser portion, that which received the shorter exposure, consisting of an allotropic modification of AgBr and the greater portion corresponding to the longer exposed, consisting of silver sub-bromide, which was formed by the evolution of bromine. Lately he has given this up as not well founded, and supports the subhaloid theory.

Organic and Inorganic Images.

Hardwich, and, later, Sterry assume two chemical substances in the latent image, an inorganic and an organic; the inorganic substance should, according to this theory, be destroyed by hypo, the organic, not. This theory was founded by Hardwich on some experiments which were badly carried out. He erroneously believed that pure silver iodide collodion films lost the latent image on fixation, and that a developable image only remained on the films mixed with organic substances such as albumen, etc.; and therefore held the organic substance as an important constituent of the latent image. Actually the silver iodide film left, after fixation, a developable image, so that Hardwich's proofs were wrong.

Sterry tried no proof, but advanced the theory that the component of the latent image on gelatino-bromide, which remains after fixation, is a decomposition product of silver bromide and gelatine, probably because he lacked another explanation of the curious behaviour of the primary fixed latent image. When one thinks, however, that not only gelatino- but collodio-bromide of silver shows exactly the same phenomenon, even in the presence of concentrated nitric acid or silver nitrate, the existence of this problematical compound of silver

subhaloid with an organic substance is extremely questionable, especially if the behaviour of the latent image on collodio-bromide is more exactly studied.

Whilst the behaviour of the synthetically prepared subhaloids to nitric acid is accurately determined, there is considerable dispute as to the behaviour of the hypothetical sub-bromide of the latent image. The reason for this is that the measurements, which are actually necessary for such complicated photo-chemical reactions, were not taken sufficiently into account; further, it appears that silver subhaloid blackened by light is of a different composition from the latent image.

The Author's Experiments.

In 1899 the author showed that certain kinds of latent image were formed on collodio-bromide in the presence of silver nitrate and nitric acid, which would withstand the action of nitric acid better than metallic silver, and this is a strong argument in favour of the subbromide theory: the formation of a latent image under the above circumstances was confirmed by Lüppo-Cramer.

Using a photometer and a constant light source, collodio-bromide plates were exposed and then treated with nitric acid, Sp. Gr. 1.4, and after five minutes the latent image corresponding to the faintest light action was destroyed, after ten minutes, still more was destroyed, but not the latent image of the strongest light action; when the plate was exposed so as to cause solarisation and a distinct coloration, nitric acid did not entirely destroy the latent image, though it instantly dissolved metallic silver. In the above experiments the image, after the nitric acid treatment, was physically developed, but it was also possible to chemically develop it, though neither the inertia nor the curve of opacities was the same.

Further experiments were made as to the action of nitric acid on the solarised image, using afterwards both physical and chemical development, and the author comes to the following conclusions: (1) The normal briefly exposed latent image on pure collodio-bromide is destroyed by nitric acid; (2) the longer exposed latent (negative) image is not destroyed but only weakened; (3) the solarised latent (positive) image is only slightly attacked by dilute nitric acid, but is completely destroyed by strong acid so that it develops as a thin negative and not a positive. The opacity is dependent on the insolation, the thickness of the film and the method of development, and the image is probably due to the superposition of two different latent images.

If silver nitrate is added to the collodio-bromide, solarisation requires about ten times longer exposure than with a plain emulsion, and the sensitiveness is increased from twice to four times; if the plate is subsequently treated with nitric acid it is gradually destroyed and perfectly clean negatives are obtained.

The Physical Development of the Primary Image.

If a latent image is produced on iodide, bromide, or chloride of silver by a short exposure and then fixed with hypo, the film of bromide will be absolutely dissolved, the plate will be quite blank, and there will not be the slightest trace of an image, but physical development will give a picture. This fact, the author points out, was first noted by Young in 1858, and by Davanne and Bayard in 1859. As physical developers, that is solutions which contain metallic silver in statu nascendi, will deposit the same on any precipitate or particle or altered surface, their action cannot be held to be any support as to the chemical nature of the "grain" theory.

It is interesting to note that fixation of the primary latent image

with hypo, only destroys what we should call the details in the shadows and lessens the opacity of the half tones, in other words it shows the plate, but the action is dependent on the exposure, the developer, and the duration of development. It is obvious that, from the extremely minute traces of this "Bildüberbleibsel," which we can only call "remnants of the latent image," or *x*, which exist in the film, it is impossible to subject it to chemical analysis, therefore one must consider the results of various reagents.

The disputed assumption that the remnant of the latent image after fixation is silver, was suggested by Lüppo-Cramer, as all silver solvents destroyed it, and treatment with bromide prevented development, but if this bromised *x* was re-exposed it could be developed. Other experimenters stated that chlorising agents as well as ferricyanide destroyed this *x*.

The author's experiments proved that nitric acid, even dilute of Sp. Gr. 1.2, attacked *x* much more strongly than before fixing, and it was only in the more exposed parts that it was able to withstand the action of the acid for some time. When the latent image was treated with a 20 per cent solution of hypo at 80 degrees C., it was not destroyed but so altered in constitution after five or ten minutes that it was completely destroyed by nitric acid.

When collodio-bromide was enormously overexposed, then fixed with hypo and physically developed, a negative of a blue-grey colour was obtained, which was the negative of the second order; the less strongly exposed places developed as a positive, whilst the shortest exposed developed as a normal negative of the first order. If after fixation this enormously overexposed (3,000 to 20,000 times) part was treated with dilute nitric acid, Sp. Gr. 1.20, the image substance (metallic silver?) of the second order dissolved, and left behind a tolerably distinct solarisation image, although partially destroyed, which with physical development gave a clear and distinct positive of a brownish colour, where previously the blue grey negative of the second order existed.

Photo-Mechanical Notes.

An Opportunity for Patriotic Photo-engravers.

HIS MAJESTY'S Stationery Office recently invited tenders for Photo Zinco Blocks, and the conditions of the contract are set forth on a form issued from Westminster, S.W. This states that the contractor shall have a convenient office in London, and shall produce such photo-zincographic blocks as may from time to time be required, at the prices stated in a schedule annexed. But these prices may be increased or diminished in any tender made.

We should hardly think there is likely to be any diminution in the price, since the 28,000 blocks annually required by the "Patent Office Journal," which blocks may be as large as 8 by 5½ inches in size, are priced at 1s. each! Other line blocks are priced at 3d. per square inch with a minimum of 6d.! Half-tone blocks are 6d. per inch, with a minimum of 5s., which, if there was a fair quantity of the work, would not be unreasonable.

For making a drawing the charge is to be 6d. per square inch, and for touching up (when instructed only) the charge is to be 1½d. per square inch, the charges to be upon the completed block and not upon the drawing. All blocks to be squarely and firmly mounted on hard wood and made type-high, and delivery made, if required, within twenty-four hours.

It is just as well the Stationery Office indicates that some advance may be made upon these prices, as it is difficult to imagine how anything but patriotism could induce them to be undertaken at the figures stated for the line work.

A Useful Book.

One of the largest firms in the process world keeps a book in which it records all the defects encountered during the course of the work, and against the defect are recorded the remedies which were found efficient. As this book has been kept almost from the commencement of a long-established firm, and properly indexed, it is of considerable value now, as there is practically no trouble met with that cannot be referred to and promptly cured. This is a hint worth adoption, by individuals as well as by the house itself.

Negatives for Three-colour Half-tones.

We hear much about the advantages of making the colour records and screen negatives at one operation, the so-called "direct" process on collodion-emulsion or dry plates, as against the indirect method of making three continuous tone negatives for the colour records, three transparencies or prints from these, and then the screen negatives from these. Now it is true that there are nine operations instead of three in the latter case, but it may be that the operations are themselves simpler and more certain, and so the longer way round may prove to be a short cut. They think so in many of the Continental establishments, where they are convinced that the indirect method is the more economical, all things considered, while at an English firm recently, where six-colour sets had to be finished quickly, the operator to whom it was entrusted, thoroughly expert in both processes, chose the indirect method, and, incredible as it may seem, completed the screen negatives the same day. It is true that the six originals were of the same character, and all of the same reduction, so that only one focussing was needed, but, nevertheless, to make eighteen colour negatives, eighteen positives, and eighteen screen negatives in one day constitutes a "record," we should think.

An Overall for Process Workers.

The apron that process workers usually wear is not sufficient protection, particularly for the coat and shirt sleeves. At a cost of 7s. 6d. may be purchased a long holland coat which reaches below the knees and is provided with pockets, and most usefully with an inner sleeve which has an elastic band clipping it to the wrist. These are known as "furriers' coats," and we can only suggest one improvement to make them entirely suitable for the process worker, and that is a belt into which could be tucked a duster on which to wipe the hands, which otherwise are apt to be wiped on the coat itself, and so spoil its appearance.

Half-tone Estimates.

The cost of half-tone blocks is perhaps as little understood in many photo-engraving shops in England as in America, where Mr. George H. Benedict has been calling on his brother engravers to get their business management "straightened out." According to Mr. S. H. Horgan, in the "Inland Printer," one of the United States Government departments advertised for bids on some half-tone illustrations. When the bids were opened they ranged from 1,200 dols. down to 300 dols. Apparently there is just the same need in the States as here for process men to sit down and find out the conditions under which they are turning out an article of manufacture. How many process houses can dissect the net cost of producing their half-tones?

A Patented Half-tone Screen.

The wording of the specification in which protection is claimed for the Dittmann half-tone screen leaves room for further clearness of expression, but it is stated that the inventor has found "that half-tone screens are considerably improved if the tone-fields are endorsed within borderlines." Often, it is stated, "the cones of rays passing through the elements of the screen do not take a direction sufficiently in accordance with the tones, for the rough grain on the sensitive plate and the refraction caused thereby considerably affect the form and action of the cone of rays. If the tones of the screen

be enclosed by light or dark lines such a demarcation will be effected that the different cones of rays will be directed entirely according to the particular tones of the halftone image, and consequently the image will be properly decomposed, which hitherto has been impossible by means of tone screens. The screens are the invention of Theodor Dittmann, 9, Mühlenbrücke, Neumünster, Holstein, Germany.

A Litho Colour Patent.

A system of preparing the various transfers for multi-colour lithography has been patented by Franz Otto Münch, 237, Dresdner Strasse, Wilsdruff, Germany. By printing the negative in various depths on photographic, and especially on printing-out paper, by direct contact from the original negative, pictures are obtained which are not identical with each other, and simply by retouching in black and white, the pictures to be copied for the separate colour plates are worked up. This method involves considerably less expenditure of labour than ordinarily, and the original character of the picture is retained. A further advantage is the replacement of the troublesome photographic process by the much more convenient procedure of making a contact-print on printing-out paper. For example, colour-plates for a five-colour printing are made as follows:—A photograph of the original is first taken and five positives are made from it, for instance on matt celloidin or printing-out paper, all varying in depth or strength. The darkest print serves for the production of the blue plate: the others in succession of decreasing depth, for say yellow, neutral and two shades of red, which the particular coloured impression in question is to contain. In this manner the "value" or intensity of the colour, that is to say, their relative strengths in the finished picture, is approximately produced already in the positive printing operation. The various colours are further worked out by retouching in black and white, whereby the parts are rendered lighter or darker, as required. Thus, for instance, in the blue print, those places which in the picture are to appear without blue, or at least in a very slight shade thereof, must be wholly or more or less covered with white, while those portions which are to appear in a deeper shade of blue, must be gone over in black. The same procedure is followed in the case of the "yellow," and remaining prints. Lithographers being accustomed to judge the future chromatic effects according to the colour plate in lithographic ink, that is black-brown, they will be well able to judge the chromatic effects of the printing plate to be obtained from the paper print in photographic tones. The paper pictures thus obtained and worked up, are now copied on printing plates or films by means of the camera, and these negative printing surfaces are rendered suitable for printing in the well known manner.

Photo-Engraving as a Business.

On Thursday in last week, Nov. 23, Mr. Arthur Cox, of the Arthur Cox Illustrating Company, lectured at the L.C.C. School of Photo-engraving and Lithography before a room full of students and members of the trade. He gave a very interesting intimate talk, dealing with the difficulties of the photo-engraver regarding the claims of customers in respect to wanting work in a hurry and of impossible size. He counselled specialization, both from the point of view of business and from the point of view of the operator, and stated it was still very difficult to get good men, particularly men who could prepare originals suitable for reproduction. Dealing with the question of price-cutting, he said this frequently occurred because a customer stated he had had a low price from a rival firm. If the rival firm could do the work at that price, then the firm thought they could do it a bit lower, without ascertaining whether the cost of production could permit of its being done at a profit. In many cases this was mere bluffing on the part of the customer. The rival firm had made no such low quotation. He urged, as far more impor-

tant than any association, the ascertaining of the square inch cost of the work to the photo-engraver. When he knew this, he knew exactly what he could afford to do work at, without losing money. He believed in a system of profit-sharing in the business: it would save a surprising amount of waste among the men. There was some discussion after the lecture, and a hearty vote of thanks was accorded to Mr. Cox.

AN application for patent in the improvement of photo-mechanical processes was made last week by Edward Russell Clarke, 35, Leinster Gardens, Hyde Park, London.

Patent News.

Process patents—applications and specifications—are treated in Photo-Mechanical Notes."

The following applications for patents were made between November 13 to 18.

- CINEMATOGRAPHS.—No. 23,256. Improvements in cinematograph pictures and stereoscopes. Theodore Brown, 26, Drummond Road, Bournemouth.
- CAMERAS.—No. 23,387. Improvements in photographic cameras. Charles Howell and George Lloyd Moore, 65, Chancery Lane, London.
- STEREOSCOPY.—No. 23,425. Improvements in stereoscopic apparatus. Thomas Ernest Waltham, 4, South Street, Finsbury, London.
- CHANGING PLATES.—No. 23,431. Improvements in apparatus for carrying or changing photographic plates. William Augustus Peters, Norfolk House, Norfolk Street, Strand, London.
- PHOTOGRAPHY IN THE DARK.—No. 23,447. Improved electrical lamp for photographing in the dark. William Dentith and Harry Midgely, 30, Baillie Street, Rochdale, Lancs.
- POSTCARDS.—No. 23,455. Postcard printing carrier. Henry Essingburgh Cooke, 39, London Road, Sevenoaks, Kent.
- SHUTTERS.—No. 23,488. Improvements in photographic shutters. James Albert Watts, and Houghtons, Limited, 88, High Holborn, London, W.
- STEREOSCOPY.—No. 23,591. Improvements in stereoscopic apparatus. Léon Pigeon, 111, Hatton Garden, London.
- METALLOID SURFACES.—No. 23,815. Metalloid surfaces for photographic and mechanical printing. Charles Harald Thomson, 1, Brindley Street, New Cross, London.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

- A WALKING-STICK STAND.—No. 14,462, 1905. The claim is for a "unipod" in the form of a walking-stick, the latter consisting of a hollow stand, in which a rod or tube is carried, so that the total height of the stand may be considerably greater than that of the stick as carried. George Stratten Russell, 38, Clarence Gate Gardens, Regents Park, London, N.W.
- A POSTCARD CASE.—No. 26,482, 1904. The case consists of a pair of boards, which form the front and back, and are held together by a cord or ribbon passed through two eyeleted holes. On the cord or lacing between the two covers are threaded a number of perforated gummed tabs (5) of tough material. Two tabs arranged side by side are provided for each card, so that they

will not be permitted to turn in the binder. The cards are secured in the binder by pasting to each card the pair of tabs which will serve to retain that particular card in place. Belle

Rockwell Hixson, Primrose Hall, Market Street, Altrincham, Manchester.

DEVELOPING P.O.P.—No. 11,452, 1905. The patent is (1) for the addition to solutions for the development of partially printed P.O.P. of alum, etc.—to alter the colour of the image—and (2) for the use of a bisulphite or mixture of alkaline sulphite, and an acid in place of organic acids or alkaline sulphites in excess. Suitable developers containing alum or other salts are:—

Pyro	$\frac{1}{2}$ ounce.	15 grammes.
Soda sulphite	310 grains.	20 grammes.
Alum	$1\frac{1}{2}$ ounces.	50 grammes.
(Or aluminium sulphate, 80 to 150 grains	5 to 10 grammes).	
Water to make	35 ounces.	1,000 c.cs.

The tone of the developed print is violet or blue.

Gallic acid	$\frac{1}{2}$ ounce.	15 grammes.
Sodium sulphite cryst.	150 grains.	10 grammes.
Sodium acetate	1 ounce.	30 grammes.
Manganese sulphate... ..	80 grains.	5 grammes.
Water	35 ounces.	1,000 c.cs.

The tone is blue or violet, whereas without the manganese it is yellowish-red.

In regard to the second claim, the inventor employs a bath containing an alkaline citrate converted entirely into bi-sulphite by a strong acid without leaving excess of acid, a procedure for which he claims novelty, absence of sulphurisation when the prints are fixed, and absence of solvent action on nitrate of silver in the paper [? for nitrate read citrate.—Eds.]

A developer thus made is:—

Pyrogallie acid	280 grains.	18 grammes.
Sodium sulphite cryst.	280 grains.	18 grammes.
Sulphuric acid	34 minims.	2 c.cs.
Distilled water	35 ounces.	1,000 c.cs.

In this bath the acid and the sulphite are in such proportions as to produce bisulphite without any excess of either the one or the other. The improvements in the way of addition of alum (1, above) may be combined with this second part of the invention. Pierre Mercier, 95, Rue Lemerrier, Paris, France.

The following specification is open to public inspection before acceptance under the Patents Act, 1901:—

PLATE-HOLDERS.—No. 23,226, 1905. Photographic plate and film-holders. Torrani.

THE sixteenth annual exhibition of the Eton College Photographic Society will be held on November 30, December 1, 2, and 4.

New Books.

"Die Optischen Instrumente." By Dr. Moritz von Rohr. Leipzig: B. Teubner. M.1.

The author's name will be well known to every one who is at all interested in optics, and the present little work is, according to the preface, "An attempt to give the modern views of optical instruments in a simple manner. . . . The use of mathematics has been, as far as possible, avoided, but from the very nature of the subject they cannot be entirely obviated." The author is to be congratulated upon the success with which he has adhered to this plan, and the result is a work of only 120 odd pages, which conveys even to the veriest tyro a clear conception of the construction of various optical instruments, such as the photographic objectives of all types, reading glasses, and magnifiers, the microscope, the telescope, and opera and binocular glasses of all kinds. The elementary laws of optics, of vision, and perspective, upon which special stress is laid, lead one to the consideration of the instruments mentioned above, and a number of clearly drawn and fully explained diagrams elucidate any necessary point. The only objection we have to the work is that the old German characters are used for the text, but this cannot be ascribed to the author.

"Précis de Photographie Générale." By Ed. Belin. Vol. II. Paris: Gauthier-Villars.

This volume of M. Belin's excellent treatise treats on the scientific and industrial applications of photography, without any abstruse scientific or mathematical language, and in such a manner that the average reader can obtain a clear working conception of the subjects he deals with. Colour photography includes three-colour work, Lippmann's method, and Neuhaus's bleach-out process, colloidion both wet and emulsion processes, photo-mechanical work, photography by artificial light, stereoscopy, photogrammetry, cinematography, micro-photography, astronomical photography, and the manufacture of plates and papers are all included; whilst a very complete description of the various systems of photometry, actinometry, and spectrophotometry describes the latest systems. The book concludes with the collection of residues. Several full-page illustrations are given, and numerous diagrams in the text. The work is a welcome addition to our practical treatises.

"Deutscher Camera Almanach, 1906." Edited by Fritz Loescher. Berlin: Gustav Schmidt. Mk.3.50.

An annual of photographs and technical articles. The former are presented without comment. They are there to speak for themselves, and we will confess that such editorial policy commends itself to us, more than the custom of saying at least half a dozen lines for or against every reproduced picture. In some instances the photographs are required to illustrate the text—e.g., those of M. Demachy, accompanying his article on the telephoto lens in landscape work; and landscapes by Major Puyo made with the Pulligny lens. For the rest, the photographs represent all countries and all types of pictorial work. The German professionals have Perscheid, Raupp, and Weimer, among others, to show the effort being made to raise the standard of photographic portraiture, although Raupp's versatility is represented only by a group of nude boys. Weimer contributes some notes on photographing articles of vertu; and the other technical contributions include mountain photography, halation, three-colour work, photographing aquaria, shutter-testing, pinhole photography, together with a fragmentary review of recent progress. In all respects an admirable volume.

"Photographisches Hilfsbuch für Ernste Arbeit." By Hans Schmidt. Berlin: Gustav Schmidt. Mk.3.60.

We know of no book in English precisely on the lines of this well-

printed volume. Mr. Chapman Jones's "Science and Practice," perhaps, most closely resembles it in the way the why and wherefore of photography is discreetly blended with the so-called "practical" advice for which the amateur in his ignorance is presumed to crave. The author is not content with saying that such and such a lens is suitable for such and such a purpose, but he will have us to understand why it is and why other lenses are not. Similarly, he will not divorce an appreciation of the laws of perspective from the selection of a view point, and when we reach orthochromatic plates on page 152, he goes to the length of giving a test chart of blue and yellow patches for one's personal examination of plates and light-filters. A good book, the like of which might, with profit to the better understanding of photographic principles, be more largely read in this country. The volume deals only with negative-making; a second part is to approach printing processes in the same manner.

"Die Herstellung Photographischer Postkartenbilder." By Paul Hanneke. Berlin: Gustav Schmidt. Mk.2.

Official statistics for the year 1903 place the number of picture post-cards sent through the post in Germany at 1,161,000,000. Great Britain, in the same year, sent only 613,000,000, wherefore, perhaps, the Germans are before us in producing a book on the production of photographic cards. However, that fact need not distress anybody, for the present compilation is not a creditable monograph on the subject. Save that Chapter I. is given over to appliances for printing postcards, it is nothing more or less than a series of directions for the working of the various current printing processes. And in all the seventy-seven pages we cannot find a note of how to avoid or minimise markings on the address side of the cards, or how to dry the cards flat. Nor is there a word as to the recent discussions in Germany on postcard-publishers' rights to use any copyright photograph on the ground of its decorating an article of manufacture. We think Herr Hanneke, who is the author of several excellent handbooks, could have given us better than this.

A SECOND edition of Herr Fritz Loescher's "Vergrössern und Kopieren auf Bromsilberpapier" has issued from the press of Gustav Schmidt, 28, Königin Augustastrasse, Berlin, and in good German fashion sets forth the methods of illuminating the negative and holding the paper for the preparation of the enlargement. Page 46 brings us to practical directions, towards the close of which, on page 86, we are surprised to learn that the uranium intensifier is in general use for warm tones, and to find no mention made of the sulphide methods now largely used in this country. With these exceptions the book appears to have been brought in line with current practice.

"POLONIUM and the Radio-Active Elements." A reprint of this lecture before the Photographic Section of the Burton Natural History and Archaeological Society reaches us from the author, Mr. Fred W. Edwards. It is issued at threepence.

New Apparatus, &c.

MESSRS. A. E. STALEY AND Co. send us the 1906 model of their distance-finder, a pocket instrument for ascertaining with certainty the distances of objects when photographing without a focussing screen. The distance-finder is scaled to 6, 8, 10, 15, 25, and 50 feet and infinity, but can be marked to suit the camera of the purchaser. The price is a guinea.

New Materials.

Self-Toning Paper. Made by Marion and Co., Limited, 22 and 23 Soho Square, London, W.

From the sample submitted to us we find this new paper of Messrs. Marion's to give an excellent tone by fixing in a plain hypo bath without previous washing in water. The longer the immersion the cooler the tone, and one distinctive feature of the paper is the very slight over-printing which is necessary. There is very little reduction during the fixing process. By addition of a little carbonate of soda to the fixing bath, very pleasing sepia and warm tones are obtained, and in the most variety this mode of procedure should yield highly satisfactory results. The paper is sold on the basis of twenty-eight quarter-plate pieces per shilling packet.

"Mattos" Photographic Daylight Paper. Made by L. Thornton and Sons, 6, Holborn Viaduct, London, E.C.

Commercial "plain" paper has appeared spasmodically on the market during the past few years, and the trade name of the present manufacture is not entirely new as designatory of a printing paper innocent of gelatine or collodion emulsion. The "Mattos" paper, however, now under review is offered, we believe, as a new article of manufacture, capable of giving rich tones with gold or platinum, or both in combination. A trial of the paper enables us to confirm the makers' claims so far as the platinum tones. We have not subjected any prints to gold toning. The raw paper is a whatman manufacture, tough, and of agreeable texture, and imparting a rich effect to the finished print. "Mattos" is sold at 2s. per 29 x 21 in. sheet, and in packets of cut sizes on the basis of eighteen quarter-plate pieces for a shilling.

For the forthcoming season Messrs. Houghtons, Limited, have a new selection of sensitised Christmas greeting postcards, coated with either P.O.P. or gaslight emulsion. The greeting occupies half of the address side, and a packet of twelve cards with two masks sells at 9d. in "gaslight," and 6d. in P.O.P.

CATALOGUES AND TRADE NOTICES.

THE cult of the photographic postcard has received the careful attention of the Kodak Company, who have just issued a Kodak handbook (No. 3) on the subject. It describes the different styles of production of postcards, and appends a convenient list of the apparatus and materials required for the purpose.

MESSRS. A. E. STALEY AND Co. are issuing to the trade only a new list of photographic shutters supplied by them.

MR. R. W. PAUL informs us that owing to the increased sale of the Nernst-Paul high-power projector lamp, he is able to reduce the price, while also introducing several improvements in details of construction. The price of the complete form, with burner and resistance for any voltage, is now 40s., in place of 50s., and the shortened form, with separate resistances, has been reduced from 70s. to 60s.

CROYDON CAMERA CLUB.—The awards won at the Croydon Camera Club's exhibition were distributed at a concert at the Greyhound Hotel on Wednesday evening of last week by Mr. W. H. Smith, who occupied the chair. Hearty votes of thanks were passed to Mr. J. Bawcomb for the excellent musical programme he had arranged, and to the exhibition secretary, Mr. W. H. Rogers. The concert, which is the first of its kind attempted by the Croydon Club, was a great success in every way.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Dec.	Name of Society.	Subject.
1.....	Colne Camera Club.....	"Places and People in Westmoreland."
1.....	Bromley Camera Club	"Translation of Colour." Illustrated.
1.....	Leek and District Photo. Soc....	Mr. F. R. Ball.
1.....	Aberdeen Amat. Photo. Assn....	Amateur Photographer Prize Slides.
1.....	North Middlesex Photo. Soc....	Last day for handing in Slides for Annual Exhibition.
1.....	Aberdeen Photo Art Club.....	"X Rays." Demonstrated.
4.....	Canford & Forest Hill Ph. Soc.	"New Uses for Velox." Mr. A. W. Green. (Messrs. J. Griffin & Sons, Ltd.)
4.....	Barrow Naturalists' Field Club	"A Trip to Holland." Illustrated.
4.....	Wandsworth Camera Club	Mr. J. Ferguson.
4.....	Dewsbury Photo. Society	"The Platinotype Process." Demonstrated. The Platinotype Company.
4.....	Southampton Camera Club	"Hand Camera Work." Mr. Thos. Frank Brogden.
4.....	Bowes Park and Dis. Ph. Soc....	"Portraiture." Illustrated. Mr. C. H. Hewitt.
4.....	Heaton & Dis. Camera Club.....	"Portraiture." Mr. Harold Baker.
5.....	Royal Photographic Soc....	Exhibition of Members' Lantern Slides.
5.....	Glasgow Southern Photo. Assn....	"Three-colour Photography." Demonstrated.
5.....	Darlington Camera Club	Mr. J. W. Abney, K.C.B., D.C.I., D.Sc., F.R.S.
5.....	Hackney Photographic Society	Closing Date for Outings Competition.
5.....	Olley & Dis. Cam. & Art Soc.	"The Plates We Use and Why." The President.
5.....	Sunderland Camera Club	"The Photographic Lens." Mr. C. P. Goetz.
5.....	Manchester Amat. Photo. Soc.	"English Architecture from the Conquest to the Reformation." Mr. C. B. Howdill, A.R.I.B.A.
5.....	Birmingham Photo. Society....	"The Carbon Process." Demonstrated.
5.....	Thoruton Heath Photo. Soc....	Mr. John T. Carnaby, B.Sc.
5.....	Leeds Photographic Society	"Pictorial Possibilities." Illustrated and Demonstrated. Mr. J. W. Eadie.
5.....	Jersey Photographic Society	A Paper on "Portraiture," with Examples. Mr. W. Smedley Aston, F.R.P.S.
5.....	Holmfirth Photographic Soc....	A Paper. Mr. C. E. M. Bennett.
5.....	Newcastle-on-Tyne Photo. Assn.	"People and Places in Westmoreland." Mr. Percy Lund.
5.....	Brentford Photo. Society	"Orthochromatic Photography." Mr. A. Payne, F.R.P.S.
5.....	Halifax Camera Club	"Phototype." Mr. F. B. Shaw.
5.....	Burton-on-Trent Nat. His. Soc.	"Platinotype Printing." Mr. Frederick Macfadyen.
5.....	Stafford Photographic Society....	"Gun Bi-chromate." Mr. J. C. S. Mummery, F.R.P.S.
5.....	St. Helens Camera Club	"Bromide Printing Processes." Mr. J. Fred Seaman.
5.....	Sheffield Photographic Society	"Some Tenets of Art Applied to Photography." Mr. H. Barratt.
5.....	Leeds Camera Club.....	Amateur Photographer, 1905, Prize Slides.
5.....	Croydon Camera Club....	"Chromatic Plates and Colour Screens." at Gamble Institute. Mr. J. Critchley.
5.....	Leicester & Leicestershire P. Soc.	"Some Dutch Pictures." Mr. Arthur Marshall, A.R.I.B.A.
5.....	G.E.R. Mechanics' Institution....	"Oil Printing Process." Demonstrated. G. E. H. Rawlins.
5.....	Coventry Photo. Club	Lantern Night. with Explanatory Remarks from Exhibitors.
5.....	Nelson Photographic Society	"Light and Lenses." Mr. T. Brown.
5.....	Cricklewood Photo. Society	Distribution of Prizes to successful Students at Town Hall.
5.....	Edinburgh Photo. Society	Judging Summer Enlargements.
5.....	South Essex Camera Club	Lantern Slides by M. H. Hudson and Members.
5.....	Huddersfield Nat. and Ph. Soc.	"Pictorial Aim in Photography." Mr. Arch. Cochrane.
5.....	Tring Camera Club.....	Members' Print Criticism.
5.....	Hull Photographic Society	"Are Orthochromatic Plates best for Landscape Work?" showing the difference (if any) between Orthochromatic and Ordinary Plates, with 120 Slides. Mr. J. W. Charlesworth.
5.....	Hamstead Scientific Society....	Bi-Monthly Competition. Subjects: 1. Sporting. 2. Autumn Landscape.
5.....	Tunbridge Wells Ama. Ph. Assn.	Exhibition of Members' Prints and Slides.
5.....	Balham Camera Club	Annual Exhibition.
5.....	Harrogate Camera Club	"Wild Wales." Mr. G. W. Perkins.
5.....	Scarborough and Dis. Ph. Soc.	Lantern Night.
5.....	Liverpool Amateur Ph. Assn....	Yorkshire Photographic Union Portfolio.
5.....	Richmond Camera Club	Members' Lantern Slides. Criticism by Mr. A. Strangle.

MEETINGS OF SOCIETIES FOR NEXT WEEK (Continued).

Dec.	Name of Society.	Subject.
7.....	London and Prov. Photo. Assn.	Open Night.
7.....	Hastings and St. Leonards P.S.	"Switzerland." Mr. R. White Ford.
7.....	Darwen Photo. Association.....	"Orthochromatic Photography." Mr. Francis Fielding.
7.....	Pudsey and District Photo. Soc.	"The Eternal City." Illustrated. Mr. Thos. E. Green.
7.....	Wimbledon and Dist. Cam. Club	"Zigo and the Carbon Process." Demonstrated. Messrs. Illingworth & Co., Ltd.
7.....	Bolt Court School of Ph. Eng.	"The History of Colour Printing in England." Mr. R. Burch.
7.....	Chelsea and District Photo. Soc.	"Marine Photography" (R. J. Mortimer, F.R.P.S.). Mr. R. C. Gibbs.
7.....	Southport Photographic Soc....	"Enlarging and Contact Printing with Eastman's Bromide Papers." Demonstrated. Kodak, Limited.
7.....	Barrow Naturalists' Field Club.	Focus Prize Slides.

ROYAL PHOTOGRAPHIC SOCIETY.

At the meeting on Tuesday last, November 28, Major-General Waterhouse in the chair, Mr. Kenneth Mees showed a new form of spectroscope, in which he had used a diffraction grating replica on a concave surface, which has the great advantage of being very small, the focus of the grating being only 17 in., and the slit, sensitive grating and film are on the circumference of a circle, so that the grating and dark slide remain fixed and the slit is moved; and as the sensitive surface is on the circumference of the circle it is necessary to use celluloid films in a curved dark slide. The paper on "Diffraction Grating Replicas," by Mr. R. J. Wallace, which was printed in our last week's issue, was then read. Mr. Thorp, of Manchester, whose replicas are well known, was unable to be present, but sent a paper in which he described his method. He used a solution of 10 gms. of pure shredded celluloid in 700 ccs. of amyl acetate. Subsequently gratings by Messrs. Wallace, Thorp, and Ives were compared on the screen by means of the spectra of iron, lithium, strontium, etc.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

At the White Swan, Tudor Street, on November 23, Mr. H. Snowden Ward gave his paper, "Hints to Would-be Picture-Makers," illustrating it with diagrams and photographs. After the lecture the chairman (Mr. T. E. Freshwater) presented Mr. A. J. Bull with the L. and P. P. A. Henderson award 1904-5.

SUTTON PHOTOGRAPHIC SOCIETY.—The winter session of this society was opened on Wednesday, November 15, when the chairman, Hector Maclean, F.R.P.S., gave an address upon "The Aspects of Present-Day Photography."

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.—Mr. S. H. Bentley, in a lecture before this society on "Dark-room Illumination," spoke highly of the value of the "Geka Flexoid Light Filters." Examples brought forward went to prove that a special rapid ordinary plate could be subjected to the light of a No. 2 red for a period of four minutes without fear of fogging. To use these filters, Mr. Bentley had constructed a lamp with a special cooling chamber to prevent the melting of the filters, which are made of gelatine. The light given by the No. 1 yellow for bromide work was a surprise, for the quantity emitted enabled development to be done with considerable pleasure. Gentlemen in the locality of the above society will be welcomed to any of the meetings, which take place every Wednesday at the Hanley Hall, Sparsholt Road, Crouch Hill, N. The Secretary is Mr. S. C. Puddy, 87, Crouch Hill, N.

NORTH LONDON PHOTOGRAPHIC SOCIETY.—At the first members meeting of the above society, the following gentlemen were elected officers for the year ending December, 1906:—Hon. treasurer, W. T. Fleet; hon. secretary, C. H. Roberts; hon. assistant secretary, H. E. Taylor; hon. librarian, C. H. Madden; hon. lanternist, H. E. Radcliffe; committees, C. Adshead, G. Hale, E. Few, R. H. Lawton, P.

Symons, F. Odams, Rev. A. Gledhill. Although the society has only just been formed, the membership now stands at sixty-one. The hon. secretary will be pleased to send a copy of the rules and any further information required, to any gentlemen applying to 33, Riverside Road, Highbury, N.

BOWES PARK AND DISTRICT PHOTOGRAPHIC SOCIETY.—On Monday evening, November 20, Mr. E. Seymour (of Watford) gave a lecture on "Flower and Fruit Photography" before this society at Unity Hall, Wood Green. In dealing with flowers, the lecturer said that they should never be photographed immediately they are cut, but should be left for at least an hour before an exposure is made, as nearly all flowers will either open out a little or close their petals directly after cutting. For flowers that droop quickly, he recommends that a piece of very thin wire be run right up the stem; this will support the bloom, and one can bend or arrange the flower as desired. He obtained excellent rendering of colour values on ordinary plates by giving full exposure and using a strong pyro-soda-developer, such as 5 gr. of pyro to the ounce; development was usually complete in about three minutes. Platinotype was his favourite printing process, and he advocated a thin negative, such as one would make for bromide printing. The ordinary oxalate bath was used, but from two to three times the usual quantity of water was added. During the course of the evening Mr. Seymour exhibited about ninety slides through the lantern to illustrate his remarks. All his work is done in a studio, so that the lighting is under complete control, and there is no risk of movement by the wind in the subject being photographed.

SOCIETY OF ARTS.—Meeting held November 22, Professor H. E. Armstrong in the chair. Mr. F. Martin Duncan read a paper on "The Cinematograph and its Applications," in which he described and illustrated the ways in which he had himself applied animated photographs to the teaching and investigation of natural science, as well as to the popularisation of knowledge. As instances of such applications, he showed films of a devil dancer in Borneo, of Canadian industries, of the construction of a railway, and of the habits of a number of forms of animal life, including a remarkable series of pictures, exhibited for the first time, of the life and work of the wood-ant.

News and Notes.

AN Alleged Explosion.—A Paris pharmacist, who recently built a villa in the suburbs of Montélimar (President Loubet's town), has had it destroyed by a serious explosion which was audible at a distance of two miles. The damages were presumably caused by an acetylene apparatus, and are estimated at £1,600. The pharmacist was not insured: he had arranged to sign the policy on the following day.

COLUMBIA and Globe Burnishers.—Messrs. Burke and James, of Chicago, notify us that they have purchased the entire business and manufacturing plant of Jas. H. Smith and Co., makers of these well-known burnishers. Messrs. Burke and James will continue to market these standard goods.

REPLICAS of Diffraction Gratings.—Writing to "Nature" on the paper by Mr. R. J. Wallace, the full text of which was printed in our last issue, Mr. Thomas Thorp contributes some notes on his methods of preparing replicas. "It is stated (he says) that I first flood the grating with oil in my method of producing replicas. This, I may say, I have never done, except when making experiments, my procedure being exactly the same as Mr. Wallace's, viz., to flood the grating direct with the clarified celluloid solution, dry it in much

the same way, but using special precautions to ensure perfectly even drying, stripping and mounting in a similar manner to Mr. Wallace but leaving out the gelatine coating, which in my opinion is quite unnecessary. The great difference to be noted in the surface and performance of one of Mr. Wallace's first-quality average replicas and one of my own is due to the peculiarities in the surfaces of the original gratings, one of my own replicas having a brightness in the first spectrum on one side of at least four times that of the other and twice that of Mr. Wallace's replica. The grating from which the very bright replica is taken is a "Rowland" of 14,438 lines to the inch, and was formerly the property of the late Dr. Common. The original of the other is a very beautiful specimen of recent work on the Rowland engine, 15,038 lines to the inch. Now, whilst the latter when mounted on parallel plane glass gives comparatively feeble spectra, when mounted on prisms for direct-vision spectra, and tilting the prism to the angle required for the minimum deviation for the diffraction spectrum, first order, the brightness approaches that from the "Common" grating, whilst its much greater freedom from scattered light renders it very suitable for prominence and similar work, the dispersion being about equal to five 60deg. flint glass prisms in the centre of the spectrum, and decidedly greater at the red end. This increase of brightness is, of course, attributable to the form of the grooves, less interference being produced under the latter condition, and this notwithstanding the increase in dispersion. It may be of interest to some to know that I have succeeded in mounting these grating films on a perfectly flattened ring of glass, so that, by avoiding the use of glass as a base, light of very short wave-length can be examined by this means, either in the one case by transmission to about λ 2,600 or by reflection to as low as λ 1,850, and possibly lower. (The discovery of this reflective property for ultra-violet light was made by Mr. Morris-Airey, of the Victoria University, last year.) In order to examine by reflection either a partial vacuum is created behind the film when mounted on a glass ring or the film is mounted on a concave surface which, although not giving the lines of the grating their true form, gives very fair resolution. I have also succeeded in making concave replicas practically as perfect as plane ones, by rotating the grating during the driving process at such a rate that the paraboloidal curvature of the solution was practically the same as that of the grating. Anyway, the difference is so slight that when dry no rings can be seen on examining it by monochromatic light before the film is stripped from the grating. The difficulty of silvering these replicas satisfactorily has, however, prevented further progress, for the present at least. In justice to Mr. Wallace, I ought to say that, in a reply to a letter from me, he states he obtained his information from a patent I once took out in connection with the application of these grating replicas to colour photography; but the method there described is not the one I have adopted in making my replicas.

DEATH OF MR. J. H. T. ELLERBECK.—We regret to announce the death of Mr. J. H. T. Ellerbeck at Jersey, New Zealand, on October 21. The deceased gentleman was one of the first members of the Liverpool Amateur Photographic Society, and for many years president. He also wrote one of the first books for amateurs published, and was specially well known for the fine series of Norwegian views, he being one of the first well-known photographers to visit that beautiful country. Travelling the world over, he seemed to find more in Norway from a scenic view than in any other.

The syllabus of the Nottingham Camera Club for the season 1905-6 is to hand, and takes the form of a well-printed little booklet containing full particulars of the society and its activities. The hon. secretary is S. W. Barlow Vines, and the meetings are held at the Mechanics' Institute, Nottingham.

The annual exhibition of the Glasgow Eastern Amateur Photographic Association was opened on November 25, and closes to-morrow.

The following is the award list:—Class 1.—Silver plaque, W. S. Crocket; bronze plaque, James Watson; bronze plaque, Matthew Wilson; certificate, John Brough; certificate, George H. May. Class 2.—Silver plaque, James Watson; bronze plaque, Henry Coleman; certificate, Thomas B. Kirkhope; certificate, Robert Watson. Class 4.—Silver plaque, George L. McAllister; silver plaque, Robert Richmond; bronze plaque, Thomson Wood; certificate, A. Taylor. Class 5.—Silver plaque, W. S. Crocket; bronze plaque, Alexander Johnston; bronze plaque, Andrew Walker; certificate, Matthew Wilson. Class 6.—Bronze plaque, Robert Smith. Class 7.—Silver plaque, N. S. McMurtrie, Wishaw; bronze plaque, G. L. A. Blair, Paisley; bronze plaque, Maxwell Warnock, Paisley; certificate, Robert Ure, Glasgow; certificate, A. W. Hill, Shotts. Class 8.—Silver plaque, W. S. Crocket, Glasgow; silver plaque, George L. A. Blair, Paisley; certificate, Robert W. Steel, Paisley; certificate, Robert Ure, Glasgow. Championship Trophy (for best picture in Classes No. 1 to 4), W. S. Crocket.

REDHILL and District Camera Club.—The awards at the exhibition of this club on November 17 are as follows:—Class 1.—Medal, J. O. Grant; certificates, Miss S. E. Duncan, T. Haldane Harrison, and Miss Janet Reid. Class 1 (Section B).—Medal, Jarvis Kenrick; certificates, G. M. Hayton, Jarvis Kenrick, Herbert Livermore, and C. Robinson. Class 2.—Medals, Frederick Hollyer and Miss Janet Reid; certificate, J. O. Grant. Class 3.—Medal, C. Robinson; certificates, Sir Hanbury Brown and T. Haldane Harrison. Class 4.—Medal, J. O. Grant; certificate, G. E. Frisby. Class 4 (Section B).—Medal, C. Robinson. Class 5. Medals, Harold W. Lane, A. R. F. Evershed, and Walter Selfe. President's "Solar" Medal for best Member's Photograph—J. O. Grant.

Correspondence.

THE PERMANENCY OF MATT COLLODION PRINTS.

To the Editors.

Gentlemen,—One point that has not yet been brought up is that collodion paper, and especially matt-collodion, does not keep well before printing. It loses its freshness, and will not tone. I obtained some glossy paper direct from the maker in October, and twelve days later it would not tone in a separate gold bath. I believe it keeps better if kept in a press, and Dr. Kurz, of Wernigerode, in an old "Eder's Jahrbuch," recommended a preliminary bath in 40 per cent. spirits, which softens the film that has grown horny and impenetrable, aids the toning noticeably, and prevents cracking. I do not agree with one of your correspondents who says cracking comes from too fresh paper. I have always found such very elastic and pliable, but old paper cracks very easily. I believe that glossy collodion, toned in plain gold-sulphocyanide, keeps well. I have found it so, and it is an excellent paper to print views on, being more like the fine old albumen views than gelatine paper, and not so messy to handle, because the film does not melt in warm weather, and it can be mounted with blotting paper while still wet.

The correspondence you have obtained is very interesting and instructive, and I do not believe German photographers have gone into the matter as thoroughly as have the writers of these letters. I have never heard before, for instance, that prints must be rapidly dried, or that a fixing bath stronger than 10 per cent. should be

used, or that prints once dry could be exposed to dampness without further injury, or that paper toned in a gold bath alone kept a year in good shape and then gradually went to pieces.—I am, very truly yours,

W. S. DAVENPORT.

Saline 12, Bad Nauheim.

MR. HACKETT'S DEVELOPERS.

To the Editors.

Gentlemen,—There certainly are some points in Mr. Hackett's article in your last to which others besides yourselves may take exception, and I for one would like the following points made clear. I have no doubt they are clear—to some, and it may be my density which is, I believe, a photographic quantity, that I cannot grasp them.

Can a developer produce a more non-actinic image similar to a pyro-ammonia-minus-sulphite solution without stain, and is not this stain deposited *in situ* with the silver? There is an old experiment of dissolving out the silver from a pyro-developed negative, leaving the stain as a negative image.

Why are we to use the dearer anhydrous salts instead of the more common hydrated forms? If 2 drachms of the anhydrous sulphite is necessary in No. 1, and assuming that this weighs 120 grains (though this is not stated), are 15 to 20 grains of potassium metabisulphite equivalent to this?

Does potassium bromide actually produce a non-actinic image, and are citrates and chlorides stronger restrainers than potassium bromide? Certainly this is quite contrary to most of the accepted authorities, such as Eder, Hübl, Abney, etc.

Again, when metabisulphite is used as a preservative, what is formed when an alkali is added to it, and why will not formaline act as a slight accelerator?

If we analyse Mr. Hackett's normal developer—assuming that the larger quantity of No. 2 is used, and that he uses avoidupois ounces—the actually working formula is—

Hydroquinone	$\frac{3}{4}$ grain.
Pyro	$\frac{3}{4}$ "
Carbonate of soda anhydrous	5 $\frac{1}{2}$ "
Water	1 oz.

Now the above quantity of soda is equal to 14 $\frac{3}{4}$ grains of the crystal. Surely this is a very weak developer?

Again, we are told that if we do not wash the negative it will be stained yellow, although Chapman Jones, who is an authority on clean silver images in clean gelatine, states that this is the best method of making yellow-stained negatives. Surely it is an absolutely new fact that common salt—I beg pardon, dry chloride of sodium—tends to harden the film.

Finally, Gentlemen, one more question: What is the action of light on a properly fixed negative whilst being washed?—Yours faithfully,

CHEMICUS.

London, E.C., November 27, 1905.

SENSITISING WET COLLODION FOR COLOUR.

To the Editors.

Gentlemen,—Some time ago I published a method of rendering wet collodion sensitive to colour, the method consisting of bathing the sensitive plate, fresh from the silver bath, in a weak solution of eosine, and developing image in an alkaline reducer.

My first experiments were very successful, but on again trying the method after an interval, results were nil. Pressure of other duties intervened, and stopped further trials at the time. This last week, having a day of leisure in front of me, and some Mawson's collodion in good condition, I tried again, and here you have the results. No. 1 is from a normal wet collodion plate, developed with iron; No. 2 from a wet collodion plate, after sensitising in

usual way, bathed in a solution of eosine 1-1,000, after exposure developed with ortol-soda. Both plates had the same exposure, the light being incandescent gas.

No. 1 needs no comment, but No. 2 is quite remarkable—the general sensitiveness is less, but the colour-sensitiveness is striking, blue, yellow, and green being nearly the same density, and the red sensitiveness apparent.

Now, if this result can be obtained with silver iodide in such a great excess over bromide, I think it is quite feasible to suppose that with a silver bromide in excess, and the use of other dyes, as great a range of colour-sensitiveness can be made possible with wet collodion as with gelatino-bromide. Collodions are being prepared with bromide only and with bromo-iodide, and results will be submitted in due course. But in the meantime I should like some other workers to take up the method, and report progress.

Now for cause of failure: Fresh dye-bath must be used for each plate.

W. T. WILKINSON.

Goldsmiths' College, New Cross, S.E.,

November 25, 1905.

A BOOK QUERY.

To the Editors.

Gentlemen,—In reply to the questions of your correspondent, "C. R. W."—"Orr's Circle of the Sciences" appeared first in 1854-6, and, according to the British Museum catalogue did not pass into later editions. There were nine volumes in all. 2. The separate volume is evidently a revised edition, as it is paginated from 1 to 212. Its full title is "Theory and Practice of the Photographic Art, including its Chemistry and Optics," by W. Sparling. 3. It was issued in 1859 in an edition revised by Jas. Martin (afterwards assistant editor of the *BRITISH JOURNAL*), under the title, "The Photographic Art: Its Theory and Practice, including its Chemistry and Optics," but I am not aware that any later edition appeared.—Yours truly,

J. F. B.

Birmingham, November 25, 1905.

THE FREE PORTRAIT SWINDLE.

To the Editors.

Gentlemen,—It is a pleasure to me to write you re the free portrait swindle so often remarked upon in your pages, and, through you, to offer my thanks to the Professional Photographers' Association.

Some few months ago we had the free portrait dodgers in our district, the actual canvassers being two women. Unfortunately, the name of the firm did not transpire, or rather was not remembered. These women went round the middle-class houses of the town spinning the usual yarn regarding free enlargements, with the addition, however, of the statement that Brigham was doing this for an advertisement, and the photographs were enlarged by a firm in Manchester. Nothing was said about a frame, of course, though a receipt slip was given with the obligation regarding the frame mentioned in some obscure corner. This slip was presented in an envelope bearing *our* name.

We heard of this by two victimised old ladies coming and demanding from us their photographs back. Some persuasion was necessary before they saw that we had nothing to do with this low and objectionable touting business, regardless of the swindle.

Immediately on hearing this from my receptionist, who unfortunately had not taken many particulars, we wrote to the President of the P.P.A., who we knew had already dealt very successfully with these gentry, and whose experiences were dealt with in the P.P.A. circular. To his courtesy and promptitude we are greatly

indebted, for by return of post we received the matter he used in his circulars and advertisements warning the public.

Since we felt that the matter could not be improved on, we printed several neat circulars for exhibition in tradespeople's windows, and inserted a notice in each of the local papers in the news columns. We enclose one of the circulars, which may be of use to you.

We again beg to express our indebtedness to the P.P.A., whose ranks every professional should join. In legal advice alone he will get his subscription back several times over, for every professional is bound to have misunderstandings and difficulties with his clients at least once in his career.—Faithfully yours,

W. FOSTER BRIGHAM.

The Esplanade Studio, South Cliff, Scarborough,

November 24, 1905.

[We are glad to hear of active measures being successfully taken against these fraudulent canvassers. The circular referred to by our correspondent runs as follows:—

"CAUTION!!!

"'Brigham' Child Photographers find it necessary to advise their clients that the representations of men touting in their name for so-called 'free' enlargements are fraudulent and mendacious. The methods and objects of such people have been exposed again and again in the public Press, but owing to the large number of complaints recently received, Messrs. Brigham are afraid that the nature of the imposition is not generally realised. They therefore desire to caution their clients (and ladies particularly) against parting with their photographs to unknown men."—Eds. B.J.P.]

A WARNING.

To the Editors.

Gentlemen,—May I caution, through your journal, young men and ladies buying a business without thorough investigation. I know of cases that have had heartbreaking results, and to prove that it is necessary, allow me to mention that I vacated a studio and premises and removed my business. The old place was taken by a fresh comer, and within six months was advertised as an old-established business of fifty years' standing, doing over £500 a year, and inspection of books invited.

I can understand books being prepared, but how about plates, and I left nothing taken during the last seven years; the rest I wouldn't pay cartage for.—I remain, yours faithfully,

CAUTION.

November 28, 1905.

THE QUEEN'S "UNEMPLOYED" FUND.

To the Editors.

Gentlemen,—Not to be behindhand in showing our sympathy and charity for our more unfortunate brothers in trade—many of whom no doubt, will this winter be in need of some help—I beg to call your esteemed attention, and suggest to you (who are best able to bring the matter to the notice of our profession), that "A United National Photographers' Relief Fund" be initiated, in response to our beloved Queen's appeal, but that all moneys, etc., contributed to such appeal by the profession be used in helping photographic workers (of all grades and branches) only, and I feel sure such help will be forthcoming and not raised in vain.—Yours faithfully,

RALPH RUTLEY.

24a, The Grange, London, S.E., November 27, 1905.

[We have no reason to think that our correspondent's suggestion is practicable. The benevolent schemes have been discussed in our columns before, but they have been damned from the outset by the apathy of the very classes for whose benefit they would be carried into operation.—Eds. B.J.P.]

Answers to Correspondents.

- * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- J. Bailey, 73, Shirley Road, Southampton. Photograph of the Interior of the Hippodrome, Southampton.
- R. Wilkinson, The Studio, Hornsea, Yorkshire. Photograph of the Reredos and East Window, Hornsea Parish Church.
- W. French, Church Street, Wiveliscombe, Somerset. Photograph of Apple Orchard in Miverton, Somerset.
- G. Smith, 281, Lord Street, Southport. Photograph of a Crooke's X Ray Tube showing Röntgen Rays.
- W. Smith, 35, New Road, Grays, Essex. Two Photographs of Grays Parish Church (Exterior and Interior). Photograph of Palmist's Endowed Schools, Grays. Photograph of the T.S. "shufesbury" off Grays. Photograph of Grays Parish Church Exterior, 1807.

REMOVING SILVER STAINS.—Please say in your next journal what will remove red silver stains on a negative that has got wet in the printing frame.—**COLE.**

The following, from page 956 of the "Almanac," to which we would refer you for further details:—Soak in 20 grain per ounce solution of potass. iodide (or of iodine according to the persistence of the stain), wash, and transfer to potass. cyanide solution, 30 grains per ounce.

PORTRAITS.—Could you kindly direct me to where I could obtain portraits or cheap likenesses of such great men of England as Spencer, Shakespeare, Bacon, Byron, Burke, Pitt, Milton, etc.?—**GUC. PONNAMPALAM** (Ceylon).

You had better apply to the London Stereoscopic Company, Regent Street, London, W., or to W. A. Mansell and Co., 405, Oxford Street, London, W. From either you can obtain photographic copies of the portraits.

STUDIO QUERY.—I am about to build a studio 20 ft. long by 12 ft. wide, and would be pleased if you would give me a little advice on same. My garden runs from east to west. There are houses on the west and a large building on the south; the north is open from over the walls that divide the gardens. Will you kindly tell me how much glass you would put in, and how far from the end, and if any on the south side, and the end to take the sitter?—**STUDIO.**

Under these conditions, and for this width of studio, we should advise that about 4 ft. 6 in., top and side, at either end, be opaque, and the rest glass, the north side and top only being glazed. The sitter can then be placed at either end as circumstances require. If you can have the studio 3 ft. or 4 ft. longer you will find it a great convenience in taking standing figures, groups, etc.

PHOTOGRAPHS OF INDIA.—Being a reader of your journal, I find that you are always kind enough to impart advices and sug-

gestions to inquiring photographers. I therefore beg to approach you with the request of letting me know if there could be any demand of Indian representative views in your part of the globe? I have most of these in cabinet and full plate sizes, with small synopsis of their importance at the margin of each card. Also human figures of the different parts of this country, from civilised to barbarians, in different customs and tenure.—**A. C. MUKERJEE** (Doom Dooma, Assam).

There is always a demand—varying according to events—among publishers of books and papers. Your best course, we should say, would be to place your series in the hands of an agent. See our advertisement pages.

ALFRED THOMAS.—See the article by Harold Baker in our issue of October 27.

SPOILT NEGATIVE.—I intensified a negative with mercuric chloride. Whether the same was too strong or not, the plate prints spotty and mottled. Do you know of anything that would remove the intensified and mottled appearance.—**CHLORIDE.**

There is no remedy. The cause is, as you say, too strong mercury solution. Use the formula given in the "Almanac," page 956.

PYRO.—When dissolving pyro, according to instructions, it sometimes turns brown immediately. Does this have any bad effect on negatives developed with it, and, if so, of what nature?—**S.**

Certainly, it depreciates the developing power and conduces to stain in the negative.

No. 1.—Better ask for payment on a Royalty basis, say 10s. 6d. per 1,000. It is an effective picture, but you appear to hold an exaggerated view of its postcard value.

GEO. C. R.—We know of none. Better apply to the agent of Messrs. Meses-Goris et Fils, Mr. Otto Rosenstiel, 105, Cheapside, London, E.C.

COPYRIGHT.—I have a photograph brought for enlargement in the ordinary way of business, the mount of which is stamped "copyright." Does this prevent me executing the order, except at the risk of infringement. If so, how should I proceed to prove that this photograph actually is copyright?—**BROMIDE.**

You should make an agreement with your customer to indemnify you in the event of action. See the article on "Copyright" in the "Almanac," published this day.

BACKGROUND PAINTING.—Will you please tell me how to prepare unbleached twilled calico sheeting for receiving the ordinary scene-painter's water colours? Also what quantities of ingredients (whiting, black, blue, etc.) are necessary for first general coat, with main features in the rough, so that upon this the high-lights and darks can be touched up and intensified where needed without disturbing in any way the first general coat, and so that the colours will not easily rub off.—**VERITAS.**

Before painting, size the calico with:—Starch, 3 oz.; water, 10 oz. Boil until it begins to thicken, then brush it over the calico with a stiff brush. The following is an excellent colouring:—Common whiting, 12 oz.; powdered glue, 4 oz.; treacle, 6 oz.; water, $\frac{1}{2}$ gallon. When thoroughly mixed, add:—Ivory black, 1 oz.; ultramarine, $\frac{1}{2}$ oz.; red ochre, $\frac{1}{2}$ oz. Brush it over the calico with a broad, flat brush. This coating will be quite firmly fixed. 2. Write to Messrs. Winsor and Newton, Rathbone Place, or Messrs. Reeves, Cheapside. They will be able to give you the information.

FLASHLIGHT QUERY.—1. I have an order to photograph a wedding group of about fifteen persons during the Christmas week. The ceremony is to take place in a hall which is badly lighted as regards daylight. I have no lamp; what will be the best thing to do? I may say my client told me she is very nervous about flashlight. 2. What are the best books to get on the subject?

1. Why not buy a good "blow-through" flash-lamp. This form of lamp is not expensive, and is quite safe when used with plain magnesium. If you know nothing of flashlight photography, you will find this the best course. The Todd-Forrest standard lamp is a good example. 2. The "Photo-Miniature," No. 29, is a practical guide to flashlight work. Write to Messrs. Dawbarn and Ward, 6, Farringdon Avenue, E.C., for particulars of this and other works on flashlight photography.

NEWCASTLE-ON-TYNE AND OTHERS.—In our next.

LEAKY WOODEN DISHES.—For use in my dark-room I prefer wood developing dishes, with flat, fluted glass bottoms, but find that the white lead, between glass and wood, after a time begins to allow developer to leak through. Can you recommend something better than white lead—something that would withstand pyrogallic acid—for keeping dishes acid and water tight?—F. E. G.

Prout's elastic glue, melted, and run into the joints with the assistance of a hot iron, will render the dishes quite acid- and water-proof.

PHOTOGRAPHS FOR THE PRESS.—When photographs are intended for the illustrated Press, should they be sent the size in which they will be reproduced, or larger?—H. Y. Z.

The larger the better, within reason; 10 by 8 is a good average.

CRACKED VARNISH.—I have a negative which has been varnished for a number of years; the varnish now appears to be cracking. As the negative was retouched by an expert (now deceased), I do not wish to destroy this retouching by removing the whole of the varnish. Is there any method whereby a part of the varnish can be removed and replaced with fresh varnish without showing a mark that would show in printing? Or is there a way of softening the varnish and so getting rid of the cracks?—C. D. V.

We know no way of achieving your object. Why not remove all the varnish and have the negative retouched a second time? You appear to think there is no good retoucher living.

FAIRPLAY.—You can charge for the sitting only in each case; but, before moving further, we recommend you to seek the advice of the Professional Photographers' Association, 51, Baker Street, W.

ADDRESS WANTED.—Kindly inform me where I can obtain a book form frame for a Daguerreotype photograph.—J. W.

Messrs. Mander and Son, Branstons Street, Birmingham, will supply you with a Daguerreotype case. We are not sure that they stock them now, but they will supply them to order.

COPYRIGHT.—Can you tell me whether the enclosed photograph is copyright? Also if it would be safe to proceed against proprietors of paper who have issued enclosed drawing from it? I bought all copyrights connected with ———'s business, but have no record of negatives copyrighted by him. How can I proceed to get list of negatives which he has copyrighted, as he is abroad, and I cannot get his address?—HILL AND SON.

You can learn if the copyright in the portrait has been

registered by searching the register at Stationers' Hall. This will be an easy matter, as you know the name of the sitters and the name of the photographer who took it. But whether it has been registered or not, you can have no copyright in the picture, unless your predecessor assigned it to you in writing. Unless this has been done, it will be of no use to take proceedings against the paper. See the "Almanac," published to-day.

Commercial & Legal Intelligence

A "PRINCESS" of Bond Street.—Charged with obtaining miniatures and other articles, worth £77, from Messrs. Esmé Collings, Limited, photographers, of Bond Street, by falsely representing herself to be a lady of title, a fashionably-dressed woman, named Margaret True Prebble, twenty-eight, of no fixed address, was remanded at the Marlborough Street Police Court last week. Detective-Sergeant Duggan stated that in company with Inspector Drew he saw the prisoner at 5, Churton Place, Pimlico, on the previous day. Inspector Drew asked the witness whether he knew her, and he replied, "Yes, as Princess Soltikoff." To her he added, "But your real name is Margaret True Prebble." She replied, "Yes, Mr. Duggan." She admitted pawning the miniatures. They found some lady's visiting cards bearing the name "the Hon. M. Paget," and a hotel bill made out to "Lady M. Paget."

FACSIMOGRAPH COMPANY, LIMITED.—Registered November 14. Capital, £100 in £1 shares. Object, to carry on the business of photographers, photo enlargers, reproducers, etchers and printers, engravers, manufacturers and distributors of and dealers in photographs, enlargements, engravings, prints, pictures, etc. No initial public issue. The first directors are D. G. Collins, W. H. Keep, and E. A. Merekel.

STOLEN Kodak Films.—William Bozier was charged last week at the Clerkenwell Police Court with stealing two photographic films, of the value of 1s. 10d., the property of the Kodak Company, of Clerkenwell Road. The manager of the shipping department of the Kodak Company said that prisoner was a cycle messenger of the company. In consequence of having missed various articles from time to time, he set a man to watch, and he actually saw the prisoner take the films and put them in his pocket. Prisoner was brought to the witness about 9.30 in the morning, and said that he had intended to pay for them when he had his money on Friday. Since then other goods had been found, approximately of the value of 15s., which had been taken since September last. The case was remanded.

***** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

A Copy-right Surt.

An action for an infringement of copy-right in two portraits of actresses—Miss Letty Lind and Miss Fay Davis—brought by Mr. Alfred Ellis against the proprietor of the "Gentleman's Journal," was tried in the King's Bench, on Friday last. The plaintiff claimed damages and an injunction. The defence was that the infringement was an innocent one, the defendant having purchased the blocks amongst other things from the proprietors of the "St. James's Budget." In giving judgment the learned Judge, Mr. Justice Warrington, said that he would accept the undertaking of the defendant to give up the blocks and copies, which was equivalent to granting an injunction. However, he would impose a penalty of one guinea on each of the two copies, and he assessed the damages at five guineas. As the defendant had paid that sum into Court, the learned Judge ordered each side to pay their costs, so that we are afraid that the plaintiff was not much in pocket over the business. The case should be noted by country photographers who often ask us what damages they should claim when the copyright in one of their photographs has been reproduced in a local paper. If the High Court assesses the damages at five guineas for the infringement of copy-right in the portraits of two well-known actresses, reproduced as high-class blocks in a good journal, what should be claimed as damages for the infringement of the copy-right in a portrait of, say, the local squire, or, may be, the new curate by a rough sketch in the local newspaper? Country photographers, as a rule, if one of their pictures happen to be pirated, seem to have a very exalted idea as to the damages they should claim. Such a judgment as the above, we should think, will tend to discount such estimate. At the same time, we would say that we think the damages awarded to Mr. Ellis were very small, considering the value of the copyright.

Copyright Problems.

All Acts of Parliament are framed with the greatest care so as to make them as explicit as possible, but there is an old saying that none have yet been passed that a clever lawyer could not "drive a coach and four through." Be that as it may, the meaning of the clauses of many Acts have to be interpreted in the law courts. The Copyright (Artistic) Act of 1862 is a fair type of Acts generally, and there have been many legal quibbles with regard to it which the law courts have had to settle. Take, for example, the case of Nottage v. Jackson, where it was decided that the operator who took the photograph away from the studio was the author of the work and not the employer. Up to that time the employer had always been looked upon as the owner of the copyright, if it were registered in his name, and convictions for infringements were passed unchallenged. But the judgment in this case settled this point differently—and definitely. And there are still other knotted tangles of copyright law yet to be unravelled. One came up in conversation the other day with a gentleman who had spent thousands of pounds in making cinematograph records in all parts of the world. How should such films be legally protected? The films may contain many hundreds of pictures, and to register them individually would involve a considerable outlay in registration fees at 1s. each.

* * *

Copyright for Cinematograph Films.

At the time the Copyright Act was passed the cinematograph had not been invented, so the films are, of course, not referred to in it. The Act makes it illegal to copy any part of a picture, and it would clearly be illegal to copy any portion of one of the little pictures if there were a copyright in it. Supposing that a cinematograph film be registered in its entirety for the shilling fee, will that cover the copyright in the many hundred pictures it may contain? It might be argued in a Court of Law that the entire series of pictures were necessary to depict the scene as it occurred. On the other hand, it might be contested that as each picture was really complete in itself, each one should be registered separately to ensure a legal copyright. No case of the infringement of the copyright in a cinematograph film has, so far as we are aware, yet come before any of the English Law Courts, and, if one does, it will be interesting to see how it will be decided. It is very clear that if the copyright in each little picture were registered by itself, no question could arise; but what would be the result if that were not done, and the film were merely registered in its entirety? In the absence of any judgment, speculation on the part of a layman would be futile. However, it is quite possible that a case may come before the Courts, and, therefore, it will be well for those who, in the interests of photographers, are watching any new Copyright Bills in course of projection to see that in them there is some proviso with regard to cinematograph

pictures. The importance of the cinematograph among graphic methods certainly demands a proper appreciation of its position in regard to copyright.

Parcels of Portraits.

We alluded last week to the need for smart and yet neat work in mounting prints, and when the prints are mounted and finished off, the effect may be enhanced or diminished by the way in which they are despatched to the customer. Other trades recognise the importance of the appearance of a parcel or package. Seedsmen make up neatly-folded bags of seed, secured by a tie of string and sealed with a lead seal. The folding card-box, held tightly closed by two loops of string or tape, is largely used by pastry-cooks and others. An artistic business like photography should be away and ahead of all others in the neatness with which finished work is protected during delivery. When most work was mounted on a cabinet mount, with the narrowest margin, the protector wrapper was efficient, but now that much larger mounts are commonly employed a more substantial packing is necessary. Stout manilla folding wrappers, with good thick leather boards, are supplied, and not only look well, and answer their purpose, but save time in parcelling up. An alternative method for prints larger than cabinet is to use a couple of sheets of the variety of corrugated packing, in which the corrugated sheet is glued between two flat sheets, the whole being as stiff as cardboard, yet very light, and able to take up the bruise of a post-office stamp without passing it on to the contents of the parcel. The virtues of sealing-wax are not as well known to photographers as they deserve to be. A parcel is much tighter, and therefore neater if the paper is fastened as folded with parcel wax, string being used for the final fastening. There is no objection to a seal of red wax or one of the modern adhesive seals, in addition to a very neatly lithographed address label. The whole aim should be to lead the customer to feel or to say: "How nicely — sends out his portraits!"

The Surface of Platinum Prints.

A good deal of difference of opinion exists as to the finishing of platinum portraits. Some photographers find that the velvet surface of the print is much admired by their clients and they take every precaution to retain this "bloom" unimpaired. Others say that customers like a surface more approaching semi-gloss with a little finer detail, and to meet this view they roll the prints after mounting. We admit that rolling gives a semi-gloss, but we do not quite see how it can increase the detail or make it any more prominent. A poor platinum print may be improved, but if the negative is well suited to the process we certainly advise that the print be not rolled or pressed in any way. There are so many alternative methods now which give an egg-shell matt or semi-glossy surface, notably platinum-toned collodio chloride and some of the gaslight papers, that we think these should be used rather than destroy the beautiful characteristics of a beautiful process. We are not making any comparison of processes or referring detrimentally to any process, but simply urging that the distinctive effect of each process should be allowed to remain. There is probably no photographic printing process more nearly resembling mezzotint in effect than platinotype perfectly executed. It should be noted, also, that the surface of platinum prints may be much injured during the acid baths and the final washing if they are drawn out from beneath others. In changing from one bath to another, the top print should be removed, lifting it by two — not opposite — corners. If one print is dragged against another, the surface is apt to get abraded.

Spotting Platinum Prints.

One of the reasons why platinum prints are liable to abrasion in the way to which we have alluded in the previous paragraph is that the paper itself is comparatively slightly sized, and the immersion in acid baths, even of the strength of 1 part hydrochloric acid to 60 parts of water, tends to destroy some of the effect of sizing. This lack of sizing in the finished print is well known to those who have spotted or otherwise finished platinum portraits. The porous nature of the working surface causes the colour to be readily absorbed, and it is difficult to remove a faulty mark in the work. Thus, while to the beginner platinum prints are much more difficult to spot than bromides or matt C.C., the expert worker finds them easier for spotting; the colour being absorbed by the surface of the paper, causes the spotting to show much less, and second touches may be applied at once without waiting for the first to dry. There is also little or no danger of the applied colour "lifting" on a second application of the brush. For more elaborate finishing the paper is well adapted to air-brush work, and lends itself better than bromide to the use of powdered plumbago, or artist's stumping sauce, applied with a small tuft of cotton wool, principally in finishing vignettes. In colour work there is apt to be a little loss of brilliancy of colour, due to the colour sinking into the paper rather too much. Where prints have to be coloured, it may be well to size them in a plain solution of gelatine after the final washing. Owing to the different degrees of hardness of gelatine it is difficult to give a definite strength, but the sizing should on no account be so strong as to show a gloss when the prints are dry. A 3 per cent. solution of Nelson's No. 1 gelatine may be used as the basis of experiment. It will be found about right, but the amount of sizing may require adjusting to the finisher's methods of working. The same solution — warm, of course — may be applied with a brush to prints already mounted.

The Word

We may direct attention to the "Daily Photograph" of Monday last, December 4, in which Dr. J. A. H. Murray ridicules, with justifiable warmth, the suggestions of the writer whose blunder we were able to demonstrate in our last issue. Mr. Murray naturally resents the implication that the compilers of the "New English Dictionary" should not have verified statements in standard works on the history of photography, and hence the vehemence with which he applies such terms as "absurd bubble," "ridiculous blunder," to our contemporary's canard. Further confirming the facts as we stated them last week, it is interesting to learn that Dr. Murray, thinking that after all Niepce may have said something of "photographie" or "photographique," has had the original MS. examined by the Archives of Saône-et-Loire, and reports that the letter contains not a word derived from "photographie." Hence students of photographic history have still before them the task of discovering the word "photography" in any printed or written document prior to the paper of Sir John Herschel's read on March 14, 1839.

The Sale of Cyanide by Dealers.

In a Poisons Act Amendment Bill, now before the Legislative Council of New South Wales, it is proposed to permit bonâ-fide dealers in photographic materials to retail potassium cyanide for photographic purposes, such dealer, on satisfying a magistrate that he is a fit and proper person, to receive a certificate granting him the right to retail the poison. Quite possibly such a provision is more necessary in Australia than in this country, where potassium cyanide is but little used by the large majority of photographers, and where, also, the photographic dealer may often be the

only man from whom supplies of chemicals can be conveniently drawn. Yet we have always held that the photographic dealer is as well qualified to sell poisonous substances as the certificated pharmacist. He equally understands their dangerous character, and is able to observe the formalities insisted upon by the Poisons Act. The concession proposed in amendment to the Victorian Bill seems based on commonsense.

* * *

Terms of Apprenticeship.

Those who place youths as apprentices to learn photography, and those who take apprentices, will do well to duly stipulate as to what, or what not, the apprentice is to be taught. Too often an apprentice is taken with the sole object of getting work done at a quite nominal cost without any real intention of teaching him the business throughout. Frequently the tuition is confined to printing and mounting, and little else, and when the apprentice is out of his time he finds that he is only qualified to take an engagement merely as a printer. Many who take apprentices to learn photography, with the above object only in view, do not always realise that, if they do not teach the business throughout, they lay themselves open to an action for breach of contract, and for damages. A correspondent, whose letter will be seen in the "Answers" column, sends us his indenture, and says that during his apprenticeship he was not taught retouching, and on his father writing to the master on the subject, he was told that retouching was a different branch altogether, and did not come within the apprenticeship indentures. In the indenture now before us the master "covenants to instruct the said apprentice in the art, trade, or business of photography, and, by the best means that he can, shall teach and instruct or cause to be taught and instructed, the said apprentice."

* * *

Is Retouching "Photography?"

Can an apprentice be taught the "art, trade, or business of photography" if he is not taught retouching? The term "photography," as here used, is a wide one, and one would think it included retouching as it is a portrait business, unless there was a clause in the indenture excluding it. Every operator nowadays is expected to be able to retouch his own negatives if required to do so. There are retouchers, it is true, who do not take negatives, but an apprentice to learn the business of photography should be taught retouching as a part of the business as much as printing and studio work. In this latter, by the way, many apprentices get but scant tuition, though it is the most important part of professional photography. This matter is specially referred to here to point out to those who take apprentices the responsibilities they undertake, and that they are compelled by law to teach what they covenant to do, whatever that may be, and that if they fail to do it they lay themselves open to an action at law. If certain portions of the business are not to be taught, they should be mentioned in the indentures. We would also suggest that friends, when apprenticing youths, should stipulate in the indentures what they are to be taught and that in very definite terms. If his were always done there would be no after questions as to whether the contract had been properly fulfilled.

* * *

"Mixed Soda."

Recent prosecutions of retailers who have sold impure carbonate of soda as "soda crystals" or "washing soda" have induced a body called the "Metropolitan Grocers, Provision Dealers, and Oilmen's Association" to decide that the method of selling this substance should be altered. This body naively pro-

poses that carbonate of soda shall be sold as "mixed soda," and a placard displayed in the shop to the effect that it cannot be guaranteed that the washing soda is wholly composed of carbonate of soda. The association further suggests that all parcels should be labelled "mixed soda," and that this term be employed on invoices. Photographers need no further hint to avoid "carbonate of soda" so described, as it is sold by devices which give the retailer the license to supply an article which may be loaded with sulphate, and is as ineffective for development purposes as it is unsuitable for employment as a detergent.

ELECTION PHOTOGRAPHY.

It may be that by the time these lines appear in print we shall know the date of the General Election; if not, we, at any rate, are, according to the opinion of all who ought to know, within "measurable distance" of an appeal to the electorate. An election is not, fortunately, the money-making possibility it once was; there are "oldest inhabitants" in many a town or village who can remember the good old days when the possession of a vote in some pocket borough was worth golden guineas to the fortunate owner. It is but a few years ago since every hireable vehicle used to be commandeered by one party or the other to bring voters luxuriously to the poll, while those who lived away from their qualifications received first-class return tickets on the railway. All that is changed now, and a parliamentary candidate of the present day trembles lest some enthusiastic helper should tip rather too lavishly, or, in some other apparently innocent way, infringe the Corrupt Practices Act. But though all these illegitimate influences have been swept away there is yet a considerable volume of trade caused by elections, and among the people who benefit by this must be reckoned the photographers.

In the aggregate a large amount of money will be paid to photographers, and the number of men among whom the money is divided may be reckoned by hundreds. Of course, a few firms who specialise on portraits of public men will get a large share of the business, and those who turn their energies largely or exclusively to press photography will cover most of the incidents. But when an intense local interest is aroused in some five or six hundred centres at once, the local men each in their own districts are the only men to take advantage of the chance. Let us figure it out a little. There are 670 seats in Parliament, and most of them will be won only after a contest, and so we may reasonably assume that the number of candidates will be well over the 1,000 mark. Many of these men will figure in the London illustrated papers, more of them will appear in the various local papers, and probably there will not be a single one whose portrait is not reproduced in one form or another. And on an average they will appear several times. Without going to any carefully accurate estimate—a thing that is not possible—we may reasonably assume that the total number of these "reproduction rights" will run over five thousand. Dividing this number by two we arrive at the number of guineas which should be distributed among photographers. Many pounds, too, will be paid for pictures of election scenes, for though artists hold their own here, with their impressions of evening gatherings in large halls, the press photographer is more and more scoring with the superior realism of his work.

The sources of revenue are not limited to newspaper demands. Two lines, which if well managed, will bring in revenue in some districts, are postcards and photo-buttons. In regard to postcards, it should be possible to run two sets. It is not covering the ground to merely publish portraits of the candidates. The rival headquarters, the public hall in which the votes are counted, the candidates' residences (if they are local men), and, possibly,

a snapshot or two, if these can be secured in time, would go to make up sets—one for each party. Photo-buttons are used in some places, and if judiciously pushed should go in more. These lines should scarcely be advanced at the photographer's sole risk. An order from the interested parties should first be canvassed for, and this should be forthcoming, for the goods could be supplied at a very reasonable rate. Post-cards or buttons can be mechanically produced by trade firms at a tithe the cost to a photographer who makes individual prints; a glance through our advertising columns will give the names of several firms who do this work—in half-tone, collotype, or purely photographic process. Committees, and some individual enthusiasts should buy enlargements of their candidate, and a small business could be done in direct sale of photographs. To those who retail photographs at a time like the present, a word of warning may be addressed. Showcase, or window display, appeals only to people who pass; and the more window displays there are the more people will see them. And so it is a wise plan to act as merchant as well as retailer, and arrange with booksellers and stationers to place the photographs in their windows also.

A further word of caution is in order here, for few

things are more "fugitive" than election photography, and it is very easy to overstock. The moment the election is over, interest will turn to something else, and any pictures left on hand will be so much waste paper. Success will come only to the man who bestirs himself early, who obtains his orders, or, at least, carefully canvasses the possibilities before the excitement has really commenced—in short, Now. And the countryman ought to be very chary about sending prints to London papers. One paper may publish portraits of all the successful candidates, another portraits of men entering Parliament for the first time; but their space is limited, and some papers will almost ignore the candidates. Those who have a good recent portrait which they wish to sell would be well advised to drop a line to some editor, and as he may not care to speculate, it would be allowable to let him hold it for use conditional on the candidate's success. It is little use submitting a print after the candidate's fate is known. Let photographers consider an election as a business opportunity for making a little money through a period when trade is usually dislocated, and they should be successful; but let them beware lest they be carried away by a wave of enthusiasm, and so land themselves, after the wave has ebbed, amid a mass of unsold and unsellable stock.

THE PRACTICE OF THREE-COLOUR WORK.

I.

The following notes by Dr. König on some of the practical difficulties met with by three-colour workers, which appear in the current number of the "Photographische Mitteilungen," will be found of considerable interest.

The Blue Filter.

The blue filter is the least troublesome to adjust, for even when a panchromatic plate, which is extraordinarily sensitive to yellow, is used for the yellow printing negative, it will be quite sufficient if the blue filter absorbs the yellow and yellowish green. As a matter of fact, negatives of equal character will be obtained with a reddish violet and a pure blue filter. If the blue filter transmits the green up to the E line, it can still be used, for with the short exposures required for the blue, this green will not act. It is quite another matter, however, if the blue filter is damped with yellow, and requires a comparatively long exposure, so that that for the red appears comparatively short. The author has already pointed out that it is somewhat misleading to give only the relative exposures for a given set of filters with a given plate, and it is obvious that to get a true statement the necessary increase by the blue filter must be stated.

The Green Filter.

Unquestionably this is the most difficult filter to make correctly. If the extreme red is transmitted, it can do but little harm, as the panchromatic plates are not sensitive to such light. The new green filter of the Höchst dye-works absorbs also this extreme red.

In the first place, the green filter must dampen the blue so strongly that the green and yellow can act sufficiently. According to the yellow-green sensitiveness of the plates used must the damping of the blue be adjusted. With plates strongly sensitive to yellowish green, this blue damping need not be so great as with those plates which are less sensitive to yellow-green. As almost all yellow-green sensitive plates have their maximum in the yellow or yellow-green, it is also necessary to dampen the yellow or yellow-green; the time of exposure is thus naturally prolonged, and so that the green, for which the plates are always less sensitive, can thus act sufficiently.

What will be the result of pushing the damping of the blue and yellow too far? If the blue is damped too much, or if for the negative exposure an additive filter (as used for projection),

which cuts the blue out absolutely, be used, the blue will not be opaque on the red negative, so that in printing a lot of red will print in the blue, and violets will be obtained instead of blues. If we had an ideal dye for staining the blue print, such as bluish-green with as narrow an absorption band as possible, that is to say, of the greatest colour purity (as described by von Hübl in "Three-colour Photography"), we could then completely cut out the blue by the green filter, and a pure blue would be formed by the mixture of the greenish blue with the bluish red. Since, however, our blue-green dyes, which are stable to light, are not sufficiently pure, the admixture of this with red would give only a dirty colour, and therefore we must try to obtain our blue dense in the red printing negative.

If, on the other hand, we damp the yellow too much, the filter will also cut out some of the orange; and, as a result, the orange would be as little represented as the red, and would therefore be reproduced too red.

In practice it will be found more satisfactory to damp the blue rather too strongly than too little. It is obviously the lesser fault for the pure blue, which so rarely occurs, to appear a little too red, than for the green, which is so frequently met with, to be a dirty brown.

The Red Filter.

The preparation of this filter is undoubtedly much easier than that of the green. Violet, blue, and blue-green must be absolutely cut out; red, yellow, and yellowish-green must be transmitted. In conjunction with good red-sensitive plates all red filters, whether they incline to a red or yellow tint, will be satisfactory; it is only when unsatisfactory red-sensitisers are used that special attention must be paid to the red filter.

Although the spectroscope is so indispensable for testing filters and sensitisers, the practical worker must take care not to lay too much stress upon spectroscopic results. The colours of objects, which we have to photograph, are not spectrum colours, and the absorption curves of filters and the sensitising of dyes are too frequently inclined to give a false impression of the action of these things. If the results of spectroscopic tests are controlled by practical three-colour work, some odd surprises may be encountered. Two green filters, for instance, which, tested spectroscopically, show a distinct difference in the

limits of the absorption, will give with a practical test absolutely identical negatives; blue filters of the most different hues will give faultless yellow printing negatives, and so on.

The same applies to sensitisers. Ethyl-red, which in the spectrogram shows a somewhat fainter minimum in the blue-green than pinachrom, gives with a camera test, behind the same green filter with equal exposure, always less density in the green than the latter dye. Hence that it is correct to say that pinachrom is one of the best sensitisers for green. Dr. Aarland, notwithstanding the experience proved by our innumerable three-colour negatives, states that plates sensitised with pinachrom leave a good deal to be desired in the green.

The best practical test is to expose in one camera behind the one filter plates of the same mother emulsion sensitised with the different dyes. Undoubtedly that dye is the better sensitiser for practical work, which *ceteris paribus* gives with equal exposure the better negative of the two.

The Sensitisers.

Ethyl-red, introduced by Dr. Miethe, was the first dye which made a plate sufficiently panchromatic, that is, sensitive to all colours. With more careful testing, it was found that the panchromatism of the ethyl-red plates left much to be desired, for the sensitiveness scarcely extends beyond the D line. In spite of this, however, as Dr. Miethe's results have proved, excellent three-colour work can be done with ethyl-red plates, a proof of the previous statement as to the spectroscopic tests; for, from a spectrogram one can only come to the conclusion that it is impossible to use this dye for the blue-printing plate in trichromatic work.

On the other hand, we must again give the spectrogram credit. If we do not succeed with ethyl-red plates in obtaining sufficient reproduction of the deep red. In this, pinachrom has made an important advance; it gives in the extreme red not only sufficiently dense negatives, but cuts down the exposure enormously, as compared with ethyl-red. As the plates sensitised with pinachrom possess, as already mentioned, good green-sensitiveness, this dye is unquestionably, up to the present, the best panchromatic sensitiser. According to the author's latest experiments, it is advisable to omit the ammonia in sensitising with pinachrom; the plates thus prepared are not markedly less sensitive.* They work quite clean, and will keep absolutely free from fog for four months.

The ratio of exposures for the pinachrom bathed plates behind the filters made by the Höchst dye-works is as 1:4:3. As the

blue filter prolongs the exposures about four times, the total duration of exposure is about thirty-two times as long as an ordinary exposure under similar conditions.

Pinacyanol.

Although very careful experiments have been carried out by the author with the isocyanines, pinachrom has proved to be the dye which most satisfies the requirements in practical trichromatic work. In very rare cases, however, it may happen that pinachrom will not give a satisfactory reproduction of deep red or dark brown colours, as the sensitising power of this dye does not extend into the extreme red. Some of the older cyanines, especially ethyl-cyanine, act better, but the last-named, on account of its tendency to fog and forming spots, is not desirable. Pinacyanol, a new dye prepared by the Höchst dye-works, combines with the good qualities of the isocyanines a power of sensitising into the extreme red which is extraordinary. Pinacyanol forms beautiful green crystals which dissolve in water with a blue-violet colour, and in alcohol with a pure blue tint. This new dye differs from the old and the isocyanines by its stability to acids, for whilst the aqueous solutions of the older dyes are completely decolourised by the least trace of acid, a much greater quantity of acid is required to discharge the colour of pinacyanol.

Pinacyanol, used like pinachrom, gives clean-working, very sensitive plates that will keep, which, behind a red filter, require a somewhat shorter exposure than a pinachrom-bathed plate. With equal density in the whites and yellows, the blue printing negative on the pinacyanol plate shows a much better rendering of deep red.

For preparing panchromatic plates, however, pinacyanol is not otherwise applicable, for it has practically no sensitising action in the green. It is possible, therefore, to work a pinacyanol plate in a deep green light, of the tint of about the F line, with tolerable safety. For those who lay stress upon the obtention of all three-colour negatives on one plate, pinacyanol is useless. Admixtures with other dyes, such as ethyl-red, pinachrom, or erythrosine have given no useful results, for the green sensitiveness, which is with such plates so desirable, is, by the addition of pinacyanol, much lowered.

It would be, doubtless, an advance to use only one dye, which should give the same character of negative for all three negatives. As a matter of fact, hitherto erythrosine has been used for the green and cyanine for the red, and these two dyes give negatives of totally different characters, for erythrosine gives hard negatives and cyanine tends to flatness.

Pinacyanol further possesses another advantage of the isocyanines, namely, that it does not markedly alter the gradation of the plates.

THE TRIALS OF A NATURALIST PHOTOGRAPHER.

THE lot of the naturalist photographer is by no means always a happy one. Many are the difficulties and tribulations that he has to face and conquer, and rarely are his labours thoroughly appreciated. Very few people realise the amount of patience, thought, anxiety, and nerve-wearing concentration that has to be exerted in the production of really successful photographs of wild life. They do not realise that the naturalist photographer has to study for days and weeks together the creature he wishes to portray, so as to make himself thoroughly familiar with its habits of life and environment, its characteristic movements and attitudes, ere he attempts to expose the plates from which he will make his finished pictures. But it is only by acquiring this thorough knowledge, and familiarity with his subject, that he can hope to produce really truthful, lifelike, characteristic pictures, and not mere chemical, libellous sketches.

During his wanderings by land and water, in search of his models, the naturalist photographer has it in his power to make many interesting friends—two-legged and otherwise—to gather much information on country lore, and will undoubtedly meet with some laughable accidents. Some years ago I was out pond hunting for microscopical material when I met with a laughable but, for the chief performer, somewhat unpleasant accident. I had found a pond covered with a growth of various water-weeds, except for a small patch of clear water right in the centre, and which was yielding me some very interesting material. Absolutely absorbed in my work, I was standing on tiptoe at the very edge of the pond, leaning forward and trying with my collecting stick and bottle to obtain a sample of the clear water from the centre, when I suddenly received a lifting blow from the rear which sent me flying slap into the middle of the pond. Imagine my indignation when I rose to

* The decrease in sensitiveness is only one-fifth by the omission of the ammonia. See B.J.P., October 13.—Eds. B.J.P.

the surface, and began to make my way ashore covered with slime and water-weeds, to see a great, big, old billy-goat standing on the bank looking at me with the most self-satisfied expression at the entire success of his sudden charge. What I said to that venerable billy-goat, will not bear publication; it had nothing to do with photography.

On another occasion I had set up my camera at the edge of a lake among the hills, to photograph a moor-hen's nest, and was busy focussing, when I was startled by the thud, thud of rapidly approaching hoofs and the bellowing of a bull. Looking round I saw a herd of shaggy, long-horned Scotch cattle charging down the hillside straight towards me. Thinking, under the circumstances, discretion the better part of valour, I made a bolt for the nearest tree, which partially overhung the lake, and climbed up it in a hurry, leaving the camera to take care of itself. Safely seated astride a bough, I awaited the arrival of the enemy. It was a beautiful sight to see the shaggy rascals sweep down the hill, tossing their great horned heads. Down they came to the edge of the lake and into its cool, still waters, where they stood knee-deep, drinking, and blowing from their gallop. What a picture they made, and how mad I felt not to have my camera with me to photograph them! After slaking their thirst, the cattle began to look around, and one of them catching sight of the camera and tripod promptly started to investigate it. Having gazed at it from a respectful distance, he marched up and closely examined it, giving forth a snort of disapproval. Finally, after walking round it once or twice, the rascal lowered his head, and getting a horn between two of the tripod legs lifted the whole apparatus and tossed it into the lake. He then marched up to the tree in which I was perched, and had a good, comfortable rub against it, inviting me in unmistakable language to come down and follow my camera. Needless to say, I did not accept his kind invitation, and had to sit in that tree for over two hours before the herd took its departure.

While taking cinematograph pictures of wild life for Mr. Charles Urban, I have had many exciting and not always pleasant adventures; indeed, as leader of the Urban Expedi-

tion to South America last autumn, I nearly lost my life, thanks to the agency of some of those minute forms of microscopic life, whose shapes and movements have been made familiar to the public through the exhibitions of the "micro" bioscope. When I was bioscoping the taking of a swarm of bees, for a series of animated pictures of bee life, I had a very painful and lively time. It was a windy afternoon, and the bees, who greatly dislike the wind, were very angry. I had my head and face protected by a veil, but was obliged to have my hands uncovered so as to manipulate the apparatus. By the time I had got my apparatus fixed up in position for bioscoping the swarm, I was simply covered with bees, and they were crawling all over the camera. The trouble, however, did not begin until I started to take the picture; then in rapidly turning the handle of the bioscope, which feeds the films through the camera, I began to knock the bees down. Up went the hum of challenge and anger, and the bees, now thoroughly enraged, settled on my hands and began to sting right and left. The bee-farmer was at work in the act of taking the swarm, and to stop turning the handle of my camera would have meant losing the picture, for which I had tramped so far and waited so long. There was nothing for it but to set one's teeth and go ahead, every turn of the handle knocking more bees and adding to my winged foes. At last it was done, and I was able to stop and shake the bees from my hands. That night I had practically no sleep, my temperature went up, and my hands swelled to an enormous size, the fingers sticking out straight like great sausages. When I next met my bee-farming friend, and poured into his ear the tragic story of my sufferings, all the sympathy I got from him was the remark, "Well, sir, there's one thing about it, you will not suffer from rheumatism this winter. Nothing like bee stings for rheumatics!"

Such are a few of the experiences which the naturalist photographer has to go through, but the knowledge and insight which he gains by so intimate a study of Nature, will far out-weigh all the troubles and trials that he will have to encounter.

F. MARTIN-DUNCAN.

THE WEEK IN HISTORY.

Niepce's Photography in England in 1827.

WHEN Nicéphore Niepce visited his brother—Claude—at Kew in 1827, he came in contact with a Mr. Francis Bauer, a Fellow of the Royal Society, through whom he submitted an account of his heliographic work to the Society. His manuscript, however, was never placed before the society, for the reason that it spoke only of results, and not of the methods employed by the author for preparing his photo-engraved plates. It was on December 8, 1829, that Niepce drew up this document, which he entitled, "Note on some results obtained spontaneously by the action of light." He must have taken it back to France with him, because it appears with the other papers which his biographer, Fouqué, collected in 1862. Mr. Bauer, however, kept a copy, for in 1839, when the rival processes of Daguerre and Talbot began to be talked about, he gave an account of his relations with Niepce in "The Literary Gazette" of March 2. He took the view that Niepce was the inventor of the process which Daguerre was then bringing before the French scientific men, but he did so obviously before he had seen a specimen of Daguerreotype, which he would at once see to be a totally different process from that of which Niepce left him specimens.

This note of Niepce's intended for the Royal Society does not, it must be said, say anything of the real inwardness of the process, and on that ground the society were justified in refusing it, though one wonders whether they have been quite con-

sistent in this admirable policy. Practically all M. Niepce has to say is contained in the following paragraph:—"The experiments which I have the honour to present are the first results of my long researches on fixing the images of objects by the action of light, and of reproducing them by engraving processes. . . . I may claim indulgence for my work, which will be the more readily granted when it is remembered that it is the first step in an entirely new field. No doubt my designs on pewter are too feeble. The defect arises mainly from the fact that the lights do not contrast sufficiently with the shadows, resulting from the metallic reflection. It would be easy to remedy this by giving more whiteness and lustre to the parts representing the effects of light, and receiving the impressions of this latter on a silver plate well polished and browned. For then the contrast between the white and black would be more pronounced, and this last shade rendered more intense by some chemical reagent, would lose the brilliant reflection which strikes the eye with a sense of incongruity."

A Notable Advance in Daguerreotype.

Daguerre's original process, as I suppose my readers well know, consisted in the iodizing of the silver plate with vapour of iodine. It was soon found, however, that the use of Bromine with the iodine was a great aid to the superior sensitiveness of the plates. The suggestion was first made by John F. Goddard on December 12, 1840, in "The Literary Gazette." Goddard

wrote:—"Having been engaged for some time past in investigating the different means of preparing the plates for the action of light in photographic delineations of daguerreotype, in the hopes of being able to render them more sensitive, the result of my experiments has been the valuable discovery that when the bromide of iodine is used instead of the simple iodine, this very desirable object is attained in a most extraordinary degree. So delicately sensitive are the plates, when properly prepared, that the faintest light acts upon them: even on the dull, cloudy days of November, with a London atmosphere, if not too foggy, and there is sufficient light to produce a picture, it will, by a few minutes exposure, be delineated. I have not had an opportunity of experimenting with bright solar light since I made the discovery, but from the experience I have had in the old processes during the last summer, I have no doubt that with a clear summer sun in London the effects will be almost instantaneous. With the light of the ordinary gas, a picture of a plaster bust may be obtained in three or four minutes."

The Invention of Collotype.

The art of lithography, which inspired Niepce to commence his researches, also prompted Alphonse Louis Poitevin to devise the method of photo-mutamine printing, which we now know as collotype. Poitevin's process was essentially the modern collotype. His patent for it (No. 2,815) was taken out exactly fifty years ago, i.e., on December 13, 1855. He sensi-

tised stone, metal, or glass with a mixture of a colloid body, such as gum, albumen, or gelatine, with bichromate of potash. He printed under a negative, and from the exposed film prepared the surface-printing plate.

The Daguerre-Niepce Partnership.

It was on December 14, 1829, that the celebrated partnership between Niepce and Daguerre was entered into. A "provisional agreement" it was called, but Nicéphore Niepce never lived to see any other: he died four years afterwards, and his relations with Daguerre were continued by his son Isidore, as provided in the agreement. The general terms of the agreement were that each inventor should communicate to the other the results of his investigations. M. Daguerre, it is specifically mentioned, shall describe in writing a camera newly designed by him. Niepce was to hand to Daguerre a written statement of his researches, and this he did in the "Notice sur l'Héliographie," a translation of which appeared last week. Whether Daguerre ever communicated anything to Niepce is more than I can say. I know of no evidence that he did. Isidore Niepce, in his "Historique de la Découverte de la Photographie," states that his father never received any photographic print from Daguerre, but that the latter did once show him some yellowish powder which was luminous in the dark. Daguerre appears to have associated it with some possible photographic process.

HISTORICS.

SOME NOTES ON COLLODION SELF-TONING PAPER.

The combined fixing and toning bath has been called the lazy man's printing process. With greater reason this name might be applied to the use of self-toning paper. Nevertheless, these papers are so handy, and have such advantages, that many who are not lazy photographers may well use them. Absolute permanency they cannot claim. Platinum and carbon prints alone have this merit, and the latter only when the pigment used is itself permanent. I have, however, made prints and postcards on collodion self-toning paper, some of which have been exposed in a window to sunlight for several months without showing any signs of fading. Care, of course, and absolute cleanliness in working are indispensable if good results are to be obtained. There are several points in the procedure where it is easy to go wrong. If, after printing, the prints are washed in plain water, and are not kept in constant motion, and if the water is not continually changed, the silver washed out is apt to produce stains. The addition of some common salt to the water, which, however, gives a colder tone to the prints—the more salt used the colder the tone—prevents this tendency to stain. All that is needful is to see that the salt solution acts evenly. When soaking prints of a small size in salt and water, I use a dish, the area of which is four times that of the print. I place in this three prints face downwards, then turn them face upwards to see that no bubbles of air are adhering to them, then turn them face downward again, and in the same way put three more prints in, laying them on the former ones. I go on till I have three piles, each containing six prints. One corner of the dish is left free, say, the one nearest to me on the left hand. I then take the prints in the right-hand bottom pile one by one, and turning them over, place them in the vacant space. Then I bring those down from the top right-hand pile, one by one, into the now vacant right-hand bottom corner and so on, continually changing and turning over the prints in this manner for the space of five minutes; this will ensure even toning. After this, the prints

can be washed in a big basin or bath, but must not be left in a strong light or they will be stained. I once had a large batch of postcards ruined in this way. I was called away just after I had got the prints from the salt bath into the washing water, and put them under the table. A servant, seeing them there, and not approving of a basin being on the floor, put it on the window-sill in bright, diffused daylight. Every print when I came back was covered with yellow stains, which the fixing bath did not remove. After the prints are washed, I put them into the fixing bath in exactly the same manner as I put them into the salt bath, and move and turn them over in the way described above for about ten or twelve minutes; if any prints are rather too dark, they can be left a little longer in the fixing bath—this reduces them, but if they require a long immersion to reduce them, the colour suffers. After well washing, they can be dried.

The advantages of self-toning paper are:—(1) There is no danger of double-toning; (2) the process is extremely simple; and (3) if collodion paper is used, the prints can be rapidly dried before a fire.

It often happens, when loaded dark slides are carried by rail, carriage, or cycle, that pinholes caused by dust are found on the negatives. These one naturally spots out with water colour, and as a result small white spots may appear on the print. I find that the best way to touch these out on collodion paper is by using a black-lead pencil; the grey colour and slight gloss of the lead shows far less on the print than if water colour is used. The pencil, too, is very handy to use in working up the print, if a process block has to be made from it. I have, with certain kinds of collodion self-toning card, found a tendency to blister badly in the solutions, even when every precaution to keep them at the same temperature has been taken. Most of the blisters disappear on drying. If they should not, but leave little raised ridges round the margins, I immerse the card for a few seconds in water, mop off the surface moisture with blotting-paper or

a cloth, lay them on a sheet of glass, then place some transparent water-proof paper over the face of the print and rub down the blisters with the smooth handle of a knife. In this way they can be almost, if not quite, got rid of. A little practice will show how far printing should be carried. The directions generally recommend printing until the print is *slightly* darker than the finished picture is desired

to be. I however find that this is hardly enough, as the prints become considerably lighter in the fixing bath, and although they darken a little in drying, I find that prints which, when taken from the frame seem much overdone, generally give the richest results when finished.

T. PERKINS.

THE NATURE OF THE LATENT IMAGE.

The Probable Composition of the Latent Image.

It is obvious from this that a strongly overexposed image can be separated into three substances, and probably there are different kinds of silver subbromide of different chemical composition present in the latent image or possibly solid solutions of half-bromide of silver in silver bromide with constantly changing chemical and photographic properties.

When the latent image is treated with a 5 per cent. solution of potassium cyanide almost the whole of it is destroyed, so that only a very slight trace can be physically developed; if plenty of sulphite is added to the cyanide it acts less strongly, but after both methods, nitric acid destroys every trace of x, and the image cannot be physically developed. Probably the cyanide decomposes the subbromide more thoroughly into metallic silver and soluble bromide than hypo, so that nitric acid dissolves it.

Ammonia acts like hypo, but it dissolves the exposed bromide much more slowly than the unexposed, and it can be better physically developed, probably because it leaves undissolved most of the hypothetical subbromide.

Saturated solution of ammonium bromide may also be used as a fixing agent, but it attacks the less-exposed latent image, much more than hypo, which is not surprising, as Lüppo-Cramer has pointed out that solutions of bromides markedly weaken and practically destroy the latent image on collodion (reformation of the normal bromide from the subbromide).

The Silver Sulphide Theory Untenable.

In the face of the above experiments Precht's theory that the primary fixed latent image consists of a "silver sulphide grain," formed by the sulphur compounds of the fixing salt, must be rejected as the least probable of all theories.

If the collodion film be orthochromatised with any of the usual dyes and exposed in the spectrograph, and then treated as the plain collodion in the above experiments a developable x remains in the yellow green, exactly the same as in the blue and violet, we may therefore assume that in the region of colour sensitising a normal latent image is formed as in the blue and violet portions. It is questionable, however, whether this applies to the solarisation phenomena in the red region of the spectrum.

Silver iodide, using it in the form of wet collodion, behaves practically like the bromide, but chromic acid destroys the normal and the solarised latent image in about an equal degree, wherein it differs from the bromide, and hypo appears to alter the chemical constitution of the latent image on iodide, as after primary fixation with hypo, nitric acid, Sp. Gr. 1.20, destroys it completely in a few minutes.

The Authors' Conclusions.

The subhaloid theory can easily explain the complicated behaviour of the latent image to chemical agents. The substance of the normal latent image of the negative of the first order consists of silver bromide reduced in different degrees, and containing subbromide. We assume that with progressive exposure a silver subbromide is formed, as the result of the photo-chemical splitting off of bromide, which is very like the normal bromide, but which, as is seen in the ordinary negative process, is more quickly reduced to metallic silver than the

II.

unexposed bromide: this kind of subbromide is destroyed by hypo and nitric acid. With a more generous exposure, a subbromide is formed, which is the latent image of the normal negative, and is slightly attacked by nitric acid; with progressive exposure and development it gives a normal negative with a normal characteristic opacity curve. This subbromide dissolves less readily than the bromide in ammonia, ammonium bromide, and hypo, and there remains after the primary fixation of the latent image a residue which can be physically developed, but it undergoes some change. According to the nature, concentration, and temperature of the fixing solution the subbromide is more or less split up into soluble bromide and metallic silver, so that the residue consists of subbromide with more or less metallic silver. Cyanide splits it up most completely, so that only metallic silver remains.

If nitric acid is allowed to act on the primary fixed latent image, its substance is still further destroyed, especially as regards the metallic silver, as this is dissolved, so that more or less of the image substance is removed, and there remains behind some silver subbromide, the existence of which can be proved by physical development. This, however, is split up by continued action of concentrated nitric acid into soluble silver and silver bromide, which, without the action of light, cannot be physically developed, but which serves as new nuclei for physical development if it is re-exposed and thus converted into developable subbromide.

With long over-exposure of the bromide a solarised image is formed, the substance of which is, as a rule, not identical with the darkened silver bromide, which simultaneously makes its appearance, and has another chemical composition and behaviour to the substance of the normal negative of the first order.

With still stronger over-exposure and the subsequent development a negative of the second order appears, which, at least in the cases described above, consists of three substances, chemically different—namely, of metallic silver, of the substance of the solarised image, and the subbromide, the latter forming the negative of the first order. All these substances are distinguished by the well-known behaviour to photographic developers, but show also a different chemical behaviour to hypo, ammonia, nitric acid, etc. The substance formed when silver bromide blackens in the light shows a different photographic behaviour to the latent and solarised images, which can be less easily explained as a solid solution of variable quantities of half-bromide in bromide, but rather corresponds to different kinds of subbromide occurring in the films of bromide exposed for different times.

The latent image on silver iodide with excess of silver appears to consist of subiodide, which, however, is more easily split up by hypo into metallic silver and iodide than the subbromide.

The substance of the normal latent image on silver bromide is in its qualitative behaviour to chemical agents independent of the wave length of the incident light. Colour sensitisers (eosine, ethyl violet, etc.) enforce on the silver bromide in the light of the wave-length for which they sensitise, the same photo-chemical reaction, namely, the formation of subbromide, as the bromide itself undergoes in the blue, violet, and ultra-violet regions of the spectrum.

FOREIGN NOTES AND NEWS.

Combined Reducers.

M. COUSTET, after pointing out in the "Photo-Gazette" that if we were always sure of giving correct exposures and developing to the exactly correct stages we should have no need of intensifiers or reducers, offers some notes on the use of the correcting mediums at disposal. It is well known that the hypo and ferricyanide reducer increases contrasts and persulphate of ammonia reduces the same, and he suggests a combination of the two, particularly for flat negatives, fogged all over. Although intensification judiciously carried out may be useful in such cases, we really want to reduce the fog and reduce the high-lights. In cases, therefore, where plates have been over-exposed or over-developed, he advises the use of the following:—

Ammonium persulphate	20 gr.
Potassium ferricyanide	2½ gr.
Hypo	25 gr.
Water	1 oz.

The proportions may be altered to suit individual cases, bearing in mind that the ferricyanide acts more energetically than the persulphate. The mixture, as above, will remain clear whilst in use, but should be thrown away when done with, as it will not keep. In order to arrest the action of this bath, it is advisable to plunge the negative at the moment of correct reduction in a 10 per cent. solution of sulphite of soda. An alternative method of using these reducers is to make them up into separate solutions and place the plate alternately into each, with or without washing.

The Relation Between Visual and Chemical Absorption.

It has been a long established fact that the position of the maximum absorption of a sensitising dye does not correspond with the maximum of photo-chemical action, but that there was a shifting towards the red by about 20 wave lengths. In a series of spectrophotometric tests, undertaken by Drs. Precht and Stenger with plates sensitised by the new dyes—ethyl-red, pinachrom, homocol, orthochrom, pinaverdol, and pericol—this law is proved to hold good, and in the "Zeitschrift für Reproduktions-technik," they give a table in proof of the same.

Increasing the Sensitiveness of Bichromated Gelatine.

Although MM. Calmels and Clerc have advanced the statement that the sensitiveness of bichromated gelatine, fish glue, and albumen can be increased by the addition of some dyes, such as eosine and erythrosine, as used in dry-plate work, this has been denied by Tschérner; and now Dr. Neuhauss has been carrying out experiments on the same lines, and finds that no increase in sensitiveness can be obtained by this means.

Pyridine in Emulsion Making.

About twelve months ago a German patent, taken out by Dr. Witt, was published, in which it was stated that extremely fine grained and rapid emulsions could be obtained by using pyridine in place of ammonia for ripening emulsions, and that there was greater freedom from fog. Although plates thus prepared were placed on the market some few months ago, the reports on the same were not very favourable, it being stated that the speed was low and the grain not abnormally finer than in plates prepared in the usual way. Dr. Lüppo-Cramer has now reported on this process, and finds that pyridine is practically useless, that no high speed can

be obtained, and that emulsions prepared in precisely the same way, with and without pyridine, show but little difference in the size of the grain.

A New Transfer Paper for Carbon.

There has just been placed on the market a new transfer paper, which presents some features of novelty. It has merely to be soaked in cold water for ten seconds and the wet carbon print then squeegeed on to it. Development is effected in the ordinary way, and the wet print can then be squeegeed to any ordinary paper without any preliminary coating, dried, and the transfer paper stripped. A further advantage is stated to be that the carbon print has a protective and varnish-like film on its surface, which protects the print from dirt and accidental damage.

The Microscopic Examination of Unexposed and Exposed Films.

In the abstract of the paper by Dr. Eder, which appears on the previous page, attention is directed to that theory of the latent image which attempts to explain the same by the formation of metallic silver. Dr. Neuhauss, of Berlin, has now attacked this problem from the optical side. It is well known that by the so-called ultramicroscopic method—which was first worked out by Siedentopf and Zsigmondy, it is possible to see particles, the existence of which is otherwise unprovable; such, for instance, as the minute particles of metallic gold in homogeneous ruby glass, coloured by the same. There are extreme difficulties in the way of examining the unfixed films, for the simple reason that the more intense the light the greater the resolving power, and even ruby light of the necessary intensity is not without action on the silver salt. And, further, the solvent power, even of the best micro-objectives is not sufficient for detecting the extremely minute change in the bromide of silver molecule. There might be a possibility of detecting some change in plates which had been exposed and fixed. Such plates can, as is well known, be developed with a developer containing silver *in statu nascendi*, and there is therefore something which remains from the primary image. As the source of light, sunlight was used, for the solvent power, as already stated, depends to a great extent on the intensity of the light. The gelatine to be examined was placed in a small trough, which only held a few drops. The results were: (1) that pure emulsion gelatine, filtered through leather, shows a very large number of bright shining particles, of different sizes, close on the limits of visibility, and without decided colour; (2) the gelatine melted from an unexposed and fixed plate showed the same appearance; (3) a drop or two of gelatine melted off a plate, which had been exposed for a short time in the camera and then fixed and washed, showed precisely the same appearance as in 1 and 2; (4) a plate exposed as in No. 3 was fixed and washed, and then physically developed till just the first traces of an image were visible. A drop of melted gelatine from this plate showed innumerable brilliant yellowish specks of about the same size (metallic silver); (5) a plate was exposed without a camera for ten minutes in a room to diffused daylight. It was then fixed and washed, and showed the same appearances as in Nos. 1, 2, and 3. (6) A plate was exposed for ten minutes to direct sunlight, then fixed and well washed. The film, which had turned bluish-green, looked after fixing greyish, and in the ultramicroscope showed innumerable very bright yellowish or yellowish-red specks of practically the same

size. (7) A plate was exposed for an hour in the sun, then fixed and washed. On examination, which was extremely difficult on account of the dark colour, the film was seen to be crowded with flocculent masses of particles of the same colour as in No. 6. The experiments gave no satisfactory proof of the existence of particles in the gelatine, caused by exposures within ordinary limits. Were it possible to replace the gelatine by an optically homogeneous substance, it might be possible to count the difference in number of particles in an unexposed and an exposed plate. We can, however, say with tolerable certainty that there is no separation of metallic silver by ordinary exposures. It was only when the exposure was so prolonged that the film visibly darkened that the existence of any particles could be seen, and then these could be detected with an ordinary microscope.

Photo-Mechanical Notes.

The Levy Etch-Powdering Machine.

FROM Mr. Louis Edward Levy, of Philadelphia, we are in receipt of a circular describing a new piece of apparatus supplementing the acid blast introduced by Mr. Levy a year or two ago for the etching of zinc and copper plates. The "etch-powdering machine," as it is called, is described at length in the circular, from which we may extract some salient passages:

The machine is a mechanism for preparing zinc or other metal plates with a powdered resinoid for the process of etching. The entire manipulation of the plate, as regards the application, clearing and melting of the powder and cooling of the plate is effected mechanically, and in one operation.

With this machine a plate of any size up to 24 in. square, and of any thickness in ordinary use, can be "topped," that is to say, prepared for the first etch, in $1\frac{1}{4}$ minutes, and given a "four-way" powdering, in readiness for the next etch, in five minutes. The ground is kept cleaner, and the powdering, especially on large plates, is more uniform than is practicable

with hand-work. The "banking" of the powder, whether "wide" or "close," is, of course, primarily dependent on the nature and condition of the powder in use, but is ultimately controlled by means of a movable handle which determines the position of the brushes in relation to the plate and the degree of their pressure upon it. Apart from this preliminary adjustment, the process is entirely automatic.

The plate to be powdered is laid on the receiving table, face up, against the projecting prongs of a carrier bar; the machine is then started; a small handle is next pressed down to bring the cylindrical feed-brush into operation; the plate is now carried forward by the carrier-bar under the feed-brush, thence

onward under a gang of elliptically moving flat brushes which pack the powder on the plate and clear away the surplus, still forward through a gas furnace which melts the powder in place, and finally on to a cooling table, where the hot plate is swept on both sides by an air blast which quickly cools it in readiness for a repetition of the procedure in another direction through the machine.

Putting the plate in its proper position on the receiving table, adjusting the gang brushes if necessary, starting the machine to go and bringing the feed-brush into operation is all the etcher has to do. When the plate passes the feed-brush the latter is automatically lifted out of operation; when it reaches the furnace, the gas is automatically turned on and lighted; when it arrives at the cooling table the air blast is automatically started.

After receiving powder from the feed-brush, the plate passes under sweep-brush, A, which packs the powder against the projecting features of the plate and sweeps back the surplus until it falls into the drawers below. The plate is carried beyond the feed-hopper into a gang-brush chamber, where the powder placed against the sides of the lines by the feed and sweep-brushes is further packed in place and the surplus brushed off by six gang brushes.

The revolution of the gang-brushes draws a current of air inwards through the exit opening, over the surface of the plate as it emerges from the brush chamber. This draft of air prevents any fine particles of powder from settling on the plate and leaves the ground perfectly clear.

The figure shows the general appearance of the machine, which consists of a feed platform on the left, the powdering chamber, and the gas furnace next in order towards the right, the powdered plate finally emerges on the delivery table.

The powdering chamber is provided with a feed-screw, which delivers the powder on to the brush, by which it is distributed on the plate.

PHOTO-MECHANICAL PATENTS.

Applications for Patents.

The following patents were applied for last week:—

Improvements in photo-mechanical printing. No. 23,990. Henry Lewis Reckard, 65, Chancery Lane, London.

Improved mechanical means of inking and preparing engraved plates for direct plate printing. No. 24,104. —Thomas MacDonald, Monument Buildings, Pudding Lane, London.

Exhibitions.

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.

CONSERVATIVE instincts of the good old-fashioned sort appear to prompt the management of the North Middlesex Society. Without beat of drum and blowing upon rams' horns it performs what it appears to regard as its first and chief duty to its own members—viz., the education of all of them in all things photographic. Thus it is that the seventeenth annual exhibition is of members' work only. Many societies of the age and standing of the North Middlesex would have aimed high at a show with all the notabilities represented. That is not the way at Stanley Hall, Crouch Hill, where they believe in bringing out the talents of their own people. They might do worse, perhaps, than provide stimulus in a small selection of photographs by a few prominent exhibitors, but there is a strong preference for devoting the whole wall space to the work of as many members as possible. Who shall say the policy is not the best? The persistent well-being of the North Middlesex Society may be taken as one proof of its correctness.

The exhibits number in all 350—199 in the pictorial section, 54 "record" photographs, and 96 lantern slides, among which latter are half a dozen three-colour transparencies. The judges, Messrs. B. Gay Wilkinson and E. T. Holding made the following awards:—

No. 17 ("Supplication"), A. G. Lawson; No. 32 (Towards the Close of a Summer Day), A. G. Lawson; No. 44 (In Old Burgos), W. Pringle; No. 68 (Fish Street Hill), H. W. Fincham; No. 69 ("Granny"), A. H. Piddington; No. 74 (A Bend in the River), S. C. Puddy; No. 106 (Venice—Early Morning), R. Child Bayley; No. 124 (North Aisle, Canterbury), W. Jackson. Lantern Slides.—No. 315 (Sunshine in the Woods), S. C. Puddy; No. 318 (Sunshine and Fog), R. R. Rawkins.

The record section represents a part of the excellent work done by the society during the past year or two in preparing a series of photograph representing the fast changing features of the northern district of London, which is the scene of its activities. This branch of the work was strongly pressed upon members at the last annual dinner of the society by the president, Mr. Charles Beadle, who, with the ex-presidents, Messrs. J. W. Marchant and J. C. S. Mummery, is among the exhibitors.

TYNEMOUTH PHOTOGRAPHIC SOCIETY.

THERE were some 250 specimens on view in the Northumberland Square Hall, North Shields, last week, at the second exhibition of the Borough of Tynemouth's Photographic Society. In making their report the judges, Messrs. David Blount and Edgar G. Lee, stated that the exhibits in the class open to the federated societies of Northumberland and Durham were of exceptional merit, the technique generally being of a high standard, and they experienced considerable difficulty in making their awards. The Federation plaque was won by J. Walton, of Sunderland, for ("Morning Mists") Arthur Payne securing the silver medal for ("Border Land") and the bronze medal going to E. Urwin, Consett, for ("An Old Shoemaker"). Certificates were also awarded by the judges to C. T. Cothay, Sunderland ("Stella"), and W. S. Corrier, Tynemouth ("The Dryad"). A special award for the best print in the exhibition by members of the Tynemouth Society was won by W. Coats. The bronze medal for postcards was won by Mr. Coats, and Mr. Scott also received the commendation of the judges.

LANCASTER PHOTOGRAPHIC SOCIETY.

THE fourth annual exhibition of this society was opened on November 27. The awards are as follows:—Open Classes.—Class A

(Landscape, etc.).—Silver medal (Tugging Home), William Clayden; bronze medal (Shades of Evening), R. T. Simpson. Class B (Portraiture and Figure Studies).—Silver medal, withheld; bronze medal (Portrait in Gum), Fred Judge. Class C (Architecture, Interior and Exterior).—Silver medal (Until the Day Break), S. G. Kimber; bronze medal (Peacefully the Shadows Guard their Tomb), James Dunlop. Class D (Lantern Slides, set of four, any subject).—Silver medal (Currants), E. Seymour; bronze medal (Hoar Frost), J. Emmott.

Members' Classes.—Class E (Landscape, etc.).—Silver medal (An Autumn Morning), C. D. Baxandall; bronze medal (Lakeland), Walter Gunson. Class F (Portraiture and Figure Studies).—Silver medal (Interested), C. D. Baxandall; bronze medal (Meditation), George W. Townsend. Class G (Architecture, Interior or Exterior).—Silver medal, withheld; bronze medal (A Corner of Borwick Hall), E. O. Harris. Class H (Lantern Slides).—Silver medal (Winter), R. T. Simpson; bronze medal (A Sunlit Street), Walter Gunson. Class I (Novices, Mounted Prints only, any subject).—Photo materials to value of 10s. 6d. (Sunshine and Shadows of Life), Fred Hargreaves.

HOVE CAMERA CLUB.

THE Hove Camera Club Exhibition was open from December 1 to 6, and the full list of awards made by the judges (Messrs. C. Job, J. C. S. Mummery, and J. H. Sussex Hall) is given below. The number of exhibitors shows no falling off this year, while a finer collection of pictures in the open class, numbering in all 424, has never been seen at Hove. The exhibition was the second of the "Southern" series, and a large number of the exhibits had already been shown at Southampton. Apart from the prize-winners, very fine work came from G. H. Capper, W. Clayden (Tugging Home), S. G. Kimber, E. Seymour, E. H. Hazell, Dan Dunlop, R. Eickemeyer, jun., Douglas English, W. Farren, H. P. C. Harpur, C. W. Howdill, P. Judge, H. W. Lane (whose "Shoeing" could not have been far behind the plaque winners). O. G. Pike, W. Rawlings, Basil Schön, the Misses Tomlinson, Miss A. B. Warburg, J. C. Warburg, and many others. The Club Classes, with the exception of the landscape, were hardly up to last year's standard; but F. J. Phillips had several good things, including "The Groote Kerk, Edam," which won for him the Challenge Salver for best picture in the Club Classes. F. R. Richardson won two first prizes, his best picture being "The Portrait," a girl painting a portrait on an easel. There was plenty of promising work among new and younger members.

For the first time the exhibition was held in the Large Hall at the Hove Town Hall, the pictures looking extremely well on screens round the room. Hove believes in having an attractive lecture list, and the lecturers this year were O. G. Pike, Douglas English, F.R.P.S., E. R. Ashton, Martin-Duncan, and Ormiston-Smith.

The following is the complete award list.—Open Classes. Class A (Framed Picture, any subject).—Plaque (In an Old Harbour), A. Marshall, A.R.I.B.A.; plaque (The Shoal), F. J. Mortimer, F.R.P.S.; plaque (The Parting Glance), Mrs. G. A. Barton; plaque (A Norman Procession Path), W. A. Clark; plaque (Onora), Miss M. Silverston; plaque (Grey Morn), J. C. Batkin; plaque (The Life History of a Splash), A. C. Banfield; plaque (Fantasy), P. G. Terras; plaque (Through a Norman Arch), T. R. Somerford; plaque (Beyond), D. J. Scott; plaque (Portrait of Miss K.), Dudley Hoyt; plaque ("Intent he seemed, and pondering, future things of wondrous weight"), Miss Marion Woods; hon. mention (Into the West), W. A. I. Hensler; hon. mention (Snow Scene in a London Park), J. H. Anderson; hon. mention (The Tiffany Glass), Miss E. T. Brailsford; hon. mention (In the Evening Light, Haddon Chapel), Rev. H. R. Campion; hon. mention (Sunlit Snow), W. B. Post; hon. mention (Maternity), T. H. Head. Class B (Lantern Slides).—Plaque

(A Norman Triforium), G. J. T. Walford; plaque (A Tree in a Mist), Ellis Kelsey; plaque (At Varenna), H. Wild; hon. mention (A Stream of Light), E. R. Bull; hon. mention (A Recess in the Woods), W. A. I. Hensler; hon. mention (Currants), E. Seymour; hon. mention (Pollen of Holly Hock), Dr. G. H. Rodman.

Club Classes.—Challenge Silver (presented by W. A. Hounsom, Esq., J.P.) for the best picture in the Club Classes.—The Groote Kerk, Edam, F. J. Phillips. The President's (Alderman J. Colman, J.P.) Prizes—the first award in each Club Class.—Class J (Landscape, River Scenery, and Marine).—Plaque (Unloading Lime at Beddingham), F. R. Richardson; plaque (Let not ambition mock their useful toil), H. P. Everett; hon. mention (Watching for Smugglers), Miss V. M. Wainwright; hon. mention (On the Banks of the Maine), L. J. Steele. Class K (Portraiture and Animal Studies).—Plaque (The Portrait), F. R. Richardson; plaque (Lighting Up), F. J. Phillips; hon. mention (Swan Study), Douglas English, F.R.P.S.; hon. mention (A Busy Maid), H. H. Eltenton. Class L (Architecture, Still Life, etc.).—Plaque (The Groote Kerk, Edam), F. J. Phillips; plaque (Autumn Roses), C. S. Simpson; hon. mention (Great West Door, Lichfield Cathedral), V. E. Morris; hon. mention (A Corner of Exeter Cathedral), W. Bailey. Class M (Lantern Slides).—Plaque (Where Trespassing is not Illegal), W. White Palmer; plaque (When the Tide is Out), V. E. Morris; hon. mention (Archway, St. Ives), W. Bailey. Class N (Novices).—Plaque, W. Chater Lea; hon. mention, E. Noel Wilson.

FORTHCOMING EXHIBITIONS.

December 12.—The Scottish Photographic Federation Lantern Slide Competition. Entries to Hon. Secretary, John B. Machlachlan, Blairgowrie.

December 12-20.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 5, Pembroke Road, Portsmouth.

December-January.—Wishaw Ph. A. Hon. Secretary, Robert Telfer, 138, Glasgow Road, Wishaw.

January, 1906.—Shettleston Camera Club. Hon. Secretary, Wm. Kitson, Hawthorne Villa, Shettleston.

January, 1906.—The Dover Institute Photographic Society. Hon. Secretary, H. Plowright, 47, Maison Dieu Road, Dover.

January, 1906.—Brierley Hill Camera Club. Hon. Secretary, J. Thomas, William Street, Brierley Hill.

January 11-13, 1906.—Boston Camera Club. Hon. Secretaries, H. M. Hames and R. W. Halliday, 65, West Street, Boston.

January 13-February 3, 1906.—The Third Scottish National Salon at Dundee. Hon. Secretary, V. C. Baird, Broughty Ferry. Entries close December 30, 1905.

January 25-27, 1906.—South Essex Camera Club. Hon. Secretary, Thomas Michell, 180, Browning Road, Manor Park, E.

January 31, 1906.—Tring Camera Club. Hon. Secretary, J. Owen Raymond, Frogmore Road, Tring.

February, 1906.—Windsor Camera Club. Hon. Secretary, Thomas J. Cartland, Thames Side, Windsor.

February, 1906.—Cardiff Windsor A.P.S. Hon. Secretary, W. A. Woodward, 187, Mackintosh Place, Cardiff.

February-March, 1906.—Birmingham Photographic Society. Hon. Secretary, Lewis Lloyd, Norwich Union Chambers, Congreve Street, Birmingham.

February 3-10.—Cape Town Photographic Society International Exhibition. Entries close January 13, 1906.

February 3-February 25, 1906.—Marseilles Fourth International Salon. M. Astrer, Sec. Gen., 11, Rue de la Grande-Armée, Marseilles.

February 6-9, 1906.—Guisbrough Fine Art and Industrial Society. Hon. Secretary, George Page, 34, Westgate, Guisbrough, Yorks.

February 13-27, 1906.—Greenock C.C. Hon. Secretary, W. D. Boyd, 2, Church Place, Greenock.

February 20-21, 1906.—Royal Albert Institute, Windsor. J. W. Gooch, Hon. Secretary.

Feb. 22-24, 1906.—Bowes Park and District. Hon. Sec., H. C. Bird, 91, Whittington Road, Bowes Park, N.

February 24—March 10, 1906.—Edinburgh Photographic Society. Hon. Secretary, J. S. McCulloch, 3A, N. St. David Street, Edinburgh.

March, 1906.—Larkhall C.C. Hon. Secretary, Robert Rodger, 26, McNeill Street, Larkhall.

March, 1906.—Leicester and Leicestershire Photographic Society. Hon. Sec., W. B. Woodland, 18, Beckingham Road, Leicester.

March, 1906.—Rugby Photographic Society. Hon. Secretary, R. N. Myers, 13, Bridget Street, Rugby.

March, 1906.—Photographic Society of Ireland. Hon. Secretary, H. V. Yeo, 194, Clonliffe Road, Drumcondra, Dublin.

March, 1906.—St. Helens Camera Club. Hon. Secretary, John Glover, 14, Ormskirck Street, St. Helens.

March 3-10, 1906.—South London Photographic Society. Hon. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

March 6-20, 1906.—Glasgow Southern P.A. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

March 7-8, 1906.—Doncaster Camera Club. Hon. Secretary, T. Haigh Connor, 39, Market Place, Doncaster.

March 12-15, 1906.—Cripplegate Photographic Society.—Secretary, Fred. Leeks, 8, Barford Street, Islington, N.

March 13-14, 1906.—G.E.R. Mechanics' Institute (Stratford). Hon. Secretary, A. Woolford, 16, Grove Green Road, Leytonstone, E.

March 14-17, 1906.—Nottingham Camera Club. Hon. Secretary, S. W. Barlow Yines, Market Chambers, South Parade, Nottingham.

March 19-24, 1906.—Sunderland Photographic Association. Hon. Sec., William E. Kieffer, Stirling Street, Sunderland.

April, 1906.—Barrhead Amateur Art Club. Hon. Secretary, R. Murray, 146, Main Street, Barrhead.

April 1, 1906.—Coatbridge Co.-Op. C.C. Hon. Secretary, James Robb, 6, Windsor Terrace, Blenheim, Coatbridge.

April 20-21, 1906.—Watford Photographic Society. Hon. Secretary, C. J. Trevarthen, Ashcroft, Bushey Hall Road, Watford.

May, 1906.—Warrington Photographic Society. Hon. Secretary, A. C. Smithson, 13, Chester Road, Warrington.

FORTHCOMING COMPETITION.

December 30.—Royal Photographic Society "Affiliation" Lecture Competition: (a) Illustrated lecture descriptive of a tour (b) Illustrated technical lecture. Particulars from the Secretary R.P.S., 66, Russell Square, London, W.C.

CATALOGUES AND TRADE NOTICES.

FREE Samples of Red Seal Plates.—Messrs. Elliott and Sons have just issued an attractive circular to professional photographers for the purpose of drawing attention to the merits of the Barnet Red Seal Plate for studio work during the dull days of winter. An opportunity for testing the merits of these fine plates is offered in the shape of free samples, which will be sent on application. The Red Seal plate, on the rapidity of which we recently commented, is sold at popular prices, and liberal discounts will be allowed to professional photographers.

MESSRS. GAUMONT and Co. have sent us their latest catalogue of new bioscope productions. The films listed include many popular subjects, and are not expensive. Cinematographers should write for a copy of this booklet to 22-27, Cecil Court, London, W.C.

New Materials.

"Bromyl" Paper. Sold by F. Douet, 6, Wellock Road, Chiswick.

This is quite a new kind of P.O.P., which is stated to be prepared with silver bromide according to the method of Dr. Foucault.

Printing under a negative composed of a series of opacities ranging in geometrical progression from 1 to 1,024, the latter corresponding to an H. and D. density of 3.1, which is much more than is usually met with in any negative, we find that the full scale will print out. The paper is, therefore, very suitable for obtaining soft results from harsh negatives.

The paper must be over-printed, as there is some loss in the lighter tones when the prints are merely fixed, but if toned with gold, or platinum, this is not so apparent. The range of colours obtainable is very great according to the method of treatment, and vary between a deep black with a trace of purple, through purple brown, sepia, and French greys.

We find the paper to be about six times faster than a P.O.P. made with citrate and chloride of silver, to daylight; but by gaslight there is practically no comparison, as ordinary P.O.P. when exposed under the above-mentioned actinometer, showed but a very faint image under the lighter squares, with half an hour's exposure at six inches from an incandescent gas burner. The "Bromyl" paper, however, printed out the full range of gradation and intensity in the same time.

The paper may be obtained with glossy, matt, and rough surfaces, and also in the form of postcards, and we are bound to describe it as a noteworthy addition to the printing papers at present on the market.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for Patents were made between November 20 to 25:—

VIGNETTERS.—No. 23,875. A vignetting attachment for photographic cameras. John Williams, 36, Chancery Lane, London.

ENLARGING.—No. 24,101. Improvements in enlarging or reducing apparatus. Gaston Clement and George Gilmer, Birkbeck Bank Chambers, Southampton Buildings, Chancery Lane, London.

PRINTING APPARATUS.—No. 24,120. Improvements in photographic printing apparatus. Albert Ashby, Frederick Horace Ashby, Major William Carter, and Edwin John Fletcher, Birkbeck Bank Chambers, Southampton Buildings, Chancery Lane, London.

LENSES.—No. 24,391. Improvements in photographic lenses. Harold Dennis-Taylor, Buckingham Works, Bishopill, York.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W. O.

PRINTING FRAMES.—No. 3,375, 1905. The invention consists of a pair of hinged boards, one provided with a central opening, rabbetted round the edges, and the other with a raised portion fitting in the rabbetted opening. The construction of the frame will be seen from the drawings. Figure 1 shows the frame open, and with springs E2 and E3 to keep the printing paper in place on the negative. Figure 2 shows the section of the frame with

the two parts brought together. Edward Rosell Petrie, 76, Second Place, Brooklyn, U.S.A.

Fig. 1.

Fig. 2.

CINEMATOGRAPHS.—No. 7,482, 1905. The invention is for a system of cinematographic projection by means of two plane mirrors, forming a right angle, and moving at its edge in a direction at angle of 45 degrees, with each face, and with a speed equal to half that of the film. Figure 1 explains the principle of the system.

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

Referring to Fig. 1, M N and N P are two plane mirrors arranged at right angles to each other and at right angles to the plane of the figure. Let A. represent a luminous point; its image with respect to the mirror M N will be at A1, symmetric to A., the image of A1. relative to N. P. will be at A2., symmetric to A1. with respect to N. P.; consequently A2. will be the final image of the point A after reflection by the two mirrors. Let it be supposed that the point A. is removed from A. to A'. upon a right line making an angle of 45deg. with each of the mirrors, and

that at the same time the combination of the two mirrors is moved parallel to this direction, a distance N , N' , equal to half of A , A' . It is evident that the image A_1 , of A , given by the first mirror will remain during this movement on the line A_1 , A_2 .

and that $I. P. = \frac{A_1, A_1'}{2}$; this will therefore give $A_1', P. = P. A_2$.

and the point A^2 will be still the image of the point A' . Consequently if any optical system L , is arranged in front of the system of the two movable mirrors, it will give from a luminous point A , moving under the conditions above stated an immovable image which will be exactly the image of the point A_2 . The above reasoning may be extended to a collection of points constituting any object or a drawing, the system of the two mirrors will always substitute for the collection of movable points of this object, an absolutely fixed image of the same size, for its distance from the nodal point of the optical system remains invariable and of the same form, for the plane of the virtual image also remains invariable. The principle is evidently reversible the optical system L will give from an exterior point an image which will move a distance double of that which corresponds to the movement of the mirrors. If A , B , represent a portion of a cinematograph film, there will be at A_1 , B_1 , a fixed image of this portion, and this image will be visible (either direct or by projection) during the whole time that the portion A , B , remains in the field of the mirrors. It is thus possible to conceive that a continuous chain of double mirrors may be arranged which will furnish at a fixed point of space a fixed image from successive images on a cinematograph film moving on the line A , A' , it is thus possible to realise the complete synthesis of movement of the subject printed on the film. It is possible also to imagine that the system of the double mirror, after having accompanied the film during a certain time, returns quickly to its first position to take a following image, which will be projected exactly at the same point as the first and so on. It is of this last means that two examples of application will be given. These means permit of continuous illumination. It would be practically difficult to retain the cinematograph film and the objective L , in the relative positions which they occupy in Fig. 1, but they can always be transferred to more convenient positions by conveniently deviating the luminous rays. This result may be obtained as shown in Fig. 2 by reflection upon two fixed mirrors K , C , H , parallel to the movable mirrors M , N , P . In this arrangement the cinematograph film D , E unrolls vertically from a roller F , and is drawn off with a continuous movement by the toothed drum T . Upon the same axis as this drum is mounted a cam J , acting upon a horizontal carriage G carrying the movable mirrors M , N , P , forming a right angle the bisecting plane of which is parallel to the film D , E . The profile of the cam J is such that when the film D , E descends a certain distance A , A' , the carriage K , is removed from this film a distance N , $N' = \frac{A, A'}{2}$. The fixed mirrors K , C , H .

are placed above the movable mirrors M , N , P , to which they are parallel, it is evident that the reflection upon these mirrors does not in any way change the principle enunciated above, and that if at the position M , N , P , of the movable mirrors, the point A , forms its image at Y , when the point has traversed the path A , A' and the mirror the path N , $N' = \frac{A, A'}{2}$ it will still form its image at Y . Thus in passing from A , A' , a certain point of the film D , E , will be constantly projected on the same point of the screen placed at Y . If A , A' is the size of an image, each of the points of this image will have during this

movement its fixed projection upon the screen and reciprocally if the apparatus is employed for taking views, each point of space will form its image at the same point of the film. After the passage of an image, the cam J , allows the carriage G , to return rapidly, it being pushed back by a spring R , during this return the objective is closed by an obturator. It will be understood that with this arrangement the cut off need only last during a very small fraction of time of exposure. Figs. 3 and 4 show in elevation and in plan another means of carrying the cinematograph film in a better position without employing extra mirrors. In this case the mirrors M , N , P , still forming a right angle, have their edges horizontal and are placed at 45deg. with relation to the axis of the lens L , they are mounted on a vertical carriage G , moved as in the preceding case by a cam or connected by gearing to the drum T , which draws forward the cinematograph film D , E , situated in a vertical plane parallel to the axis of the objective. C. K. Mills, for A. Lumiere et ses Fils 21 and 23, Chemin St. Victor, Lyon-Monplaisir, France.

PRINTING APPARATUS.—No. 3,475, 1905. The claim is for a rotatable cabinet, provided with a fixed light, and with racks for printing frames of various sizes, which are arranged horizontally to the

rays of light from the lamp. The figure shows one form of the cabinet. Kodak, Ltd., 57, Clerkenwell Road, London.

THE following complete specifications are open to public inspection before acceptance under the Patents Act, 1901:—

SUPPORTS.—No. 23,115. Supports for photographic plates of all kinds. Campagne Générale de Phonographie, Cinématographes et Apparat de Précision.

STEREOSCOPY.—No. 23,591. Stereoscopic apparatus. Pigeon.

THE Scottish Salon will have for the first time in its history the novelty of a Photographic Art Union drawing. This feature, although new to the Salon, proved very successful at the last International Exhibition promoted by the Dundee and East of Scotland Association. Mr. W. F. Hill, 18, Meadowside, Dundee, who is hon. sec. of the Art Union, will be pleased to supply tickets, and give all information.

"THE AUSTRALIAN PHOTO REVIEW," we are interested in noting, has secured Walter Burke, for its editor, and its current issue shows a commendable improvement in typography, and a general smartness of contents, for which presumably we must give Mr. Burke the credit.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Dec.	Name of Society.	Subject.
8	Watford Photographic Society	"Three-colour Work." Mr. D. Geddes.
8	Leicester Lit. and Philo. Society	Enlarged Negatives and How to Make Them. Demonstrated. Mr. A. Newton.
8	Barrow Naturalists' Field Club	"The System of the Stars" Distribution of the Stars in Space. Illustrated. Rev. T. E. R. Phillips, M.A.
8	Aberdeen Amat. Photo. Assn.	"Colour Photography." Mr. G. Robertson.
8	Glasgow Southern Photo. Assn.	Social Evening. Members and Friends.
8	Colne Camera Club	"Killarney." Mr. W. Hyde.
11	Wallasey Amat. Photo. Soc.	Lantern Lecture. Pictures taken with a Goetz Lens.
11	Oxford Camera Club	"The Property Value of Photographs." Mr. George E. Brown.
11	Widnes Photographic Society	"Combination Printing." Mr. Arthur Poole.
11	Luton Camera Club	Exhibition of Members' Work at the Club Rooms, including Pictures prepared for the Lea Valley Evening.

MEETINGS OF SOCIETIES FOR NEXT WEEK (Continued).

Dec.	Name of Society.	Subject.
14	Balham Camera Club	"Making Lantern Slides." Demonstrated. Mr. J. H. Wilkie, R.P.S.
14	Liverpool Amateur Ph. Assn.	"Orthochromatics." Demonstrated. Mr. J. W. Charlesworth.

ROYAL PHOTOGRAPHIC SOCIETY.

TUESDAY, December 5.—Major-General Waterhouse in the chair. Sir William Abney gave—before what was probably the largest audience yet gathered in the rooms—an extremely interesting demonstration, the first of a series on three-colour work. The particular point with which the lecturer dealt was the determination of the colour-filters or screens for obtaining the negatives. Particular stress was laid on the fact that the only true basis of three-colour work was colour sensimetry scientifically and rigidly followed out; rule-of-thumb methods, which were far too common, were absolutely valueless if accurate results were required. Most of the three-colour prints, which were now so widely disseminated, left a great deal to be desired, and this was due primarily to the use of improper filters, and, secondly, to deficient inks. Most methods of producing the filters were based on Maxwell's colour sensation curves, but the lecturer demonstrated the superiority of using the luminosity curves of the spectrum obtained from the positive crater of the electric arc. Abandoning his former glass screen colour sensimeter, Sir William Abney now recommended rotating templates of coloured pigments—emerald green, vermilion, chrome orange, chrome yellow, ultramarine, and Brunswick green being the colours used. These, when rapidly rotated by means of a small motor, were reduced of equal height. Having found the screens, they were then tested on Each set of colours was then matched with a spectrum colour, which gave the dominant hue of the filter. The absorption curves of the filters for the ideal panchromatic plate were then projected on the screen, and for the blue the limits were from the violet to little b, for the green from the red Li line to the blue Li line, and for the red from little b to the extreme red, the curves being practically all of equal height. Having found the screens, they were then tested on the three necessary templates, and adjusted till the same gave equal densities on the negatives. To find the necessary exposures, a white surface, illuminated by sunlight, was used as the test object, and in front of the sensitive plate was inserted strips of measured densities, and trial exposures were then made through the filters till equal density was obtained under the strips. Great importance was laid on the necessity of giving absolutely correct relative exposures, and the futility of trying to compensate for errors by subsequent faking. The practical application of the methods suggested was then proved by the projection of a series of extremely fine slides by means of the triple lantern.

SOUTHAMPTON Camera Club.—Mr. C. H. Hewitt, of the Polytechnic School of Photography, lectured on Monday evening last to the members of this club on "Portraiture." Among the points discussed by the lecturer were the following:—The difference between outdoor and indoor portraiture was shown to consist largely in the great diffusion of light in the former, which tended to general softness and difficulty of obtaining proper shadows; while in indoor portraiture the difficulty lay in dealing with the concentration of light, leading to great contrasts. Dealing first with outdoor work, Mr. Hewitt, after pointing out the correct position of the sitter in relation to light and camera, viz., the light striking the face laterally and vertically at an angle of 45 deg. to the line of sight, advised amateurs to avoid copying orthodox studio styles of portraits, and pointed out what effects might be obtained from such methods—as, for instance, the use of

a semi-translucent parasol held by the sitter—pleading, also for originality in the work. Turning to indoor photography under conditions ordinarily available for the amateur, Mr. Hewitt showed, by diagram, the right and wrong of the matter; how the usual method of placing the sitter immediately in front of the source of light, with the face in profile to that light, while the sight line from the camera made an angle of 90 deg., produced the portrait of extreme contrast, great high lights, deep shadows. Then how, with the light coming from directly behind the operator on to the sitter, was produced the flat portrait, devoid of moulding of features; and, finally, how the normally correct portrait was produced by the light reaching the face both laterally and vertically at an angle of 45 deg. from the line of sight. Mr. Hewitt then showed how a diffusing screen of tissue paper, or similar substance, interposed directly between the light and the sitter produced the half tones between the extreme high lights and shadows, and, proceeding to the further aid of a reflector to lighten the too dark shadows, pointed out the danger of cross lights. The rule laid down for this was that the reflector, of suitable description, should be so placed as to carry on the high light from its vanishing extremity without break, and in proper degree, into the shadows. Among a host of practical hints, Mr. Hewitt dealt with the matter of lack of symmetry in feature, and pointed out that in this matter the law of perspective should be regarded; that is, if, for instance, a nose were crooked or one eye lower than another, the trend of the nose or the lower eye should be the farther from the camera.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.—An extraordinary general meeting of this society was held on Thursday evening of last week, in the rooms in Eberle Street. The business before the meeting was the election of hon. secretary in the place of Mr. A. C. Butt, who had been elected to the council. Mr. C. F. Inston was proposed, and unanimously elected. Mr. James Shaw, of Manchester, then delivered his lecture, on "O'er Mountain, Lake, and Lagoon," the venue being Switzerland and Italy.

CRIPPLEGATE PHOTOGRAPHIC SOCIETY.—On November 27, Mr. J. McIntosh gave a lecture on "Intensification and Reduction," before the members of this society. He said that negatives might conveniently be divided into seven classes, thus:—1. Correctly exposed, and correctly developed; 2. Correctly exposed, but under-developed; 3. Correctly exposed, but over-developed; 4. Under-exposed, and lightly developed; 5. Under-exposed, and fully developed; 6. Over-exposed, and lightly developed; 7. Over-exposed, and fully developed. He advised for the improvement of negatives such as above the following:—1. Of course, required no after treatment. 2. Immerse and bleach the negative in a saturated solution of mercuric chloride containing $\frac{1}{2}$ per cent of hydrochloric acid. Wash the negative in a $\frac{1}{2}$ per cent. solution of hydrochloric acid, wash in plain water, and then blacken in a solution of formaline 34 minims, sodium hydrate 10 grains, water 4 ounces. Negative must remain in this bath until the image is well black, then wash thoroughly. 3. Reduce in a 2 per cent. solution of ammonium persulphate, containing $\frac{1}{4}$ per cent. of sulphuric acid; rinse in a 5 per cent. solution of sodium sulphite, wash, fix in hypo, and thoroughly wash. 4. Intensify in the following:—Mercuric chloride, 1 grain; potassium iodide, 3 grains, sodium sulphite, 40 grains; water, 1 ounce. After intensifying negative in this solution, develop it in any clean working developer, and wash. 5. Reduce in a 2 per cent. solution of ammonium persulphate, mentioned in No. 3. Intensify with the solution given in No. 4, as though negative was under-developed. 6. Intensify in (1) Mercuric chloride, 100 grains; potassium bromide, 100 grains; water, 10 ounces. Bleach in this and wash well. Then blacken in the following mixed together:—(2) Silver nitrate, 100 grains; water, 10 ounces. (3) Potassium cyanide, 100 grains; water,

one ounce. For use of 2 and 3 take sufficient of 3 to dissolve the precipitate first formed. As soon as blackening is complete, wash thoroughly. 7. Reduce in:—Sulphuric acid, 8 minims; potassium permanganate, 16 grains; water, 10 ounces.

ABERDEEN PHOTO ART CLUB.—At a meeting of this club, last week, a practical demonstration on X-ray photography was given by D. A. Christian, one of the members. Several radiographs were taken and developed—a hand requiring two minutes' exposure, and a foot, with boot on, about three minutes.

Dews and Notes.

THE Photographic Convention Winter Re-union.—As announced in our last issue, the members of the P.C.U.K. will have an opportunity of meeting at a social function, on Friday, January 12, 1906, to be held at the Galleries of the Royal Society of British Artists, Suffolk Street, Pall Mall, London, S.W. The attractions of the evening will include a reception, and an exhibition of modern paintings by British artists, vocal and instrumental music, and a little dance. Light refreshments will be provided. Invitation cards will be forwarded only to those members who have intimated their desire to be present, and will not be transferable. Members desirous of introducing friends on the occasion, may obtain visitors' tickets at 2s. 6d. each. The number, however, of these will be very limited, and early application for them is desirable. Applications for tickets should be made to the hon. sec., Mr. F. A. Bridge, East Lodge, Dalston Lane, N.E.

ROYAL Photographic Society.—At the ordinary meeting to be held on Tuesday, December 12, at 66, Russell Square, the Rev. H. W. Dick will lecture on "Art and Photography."

THE Postal Camera Club's Exhibition at the R.P.S.—This exhibition at 66, Russell Square, will remain open to the public daily, from 11 a.m. to 5 p.m., on presentation of visiting card, until January 13, 1906.

ROYAL INSTITUTION.—The following are the lecture arrangements at the Royal Institution before Easter:—A Christmas course of six illustrated lectures, adapted to a juvenile auditory, by Professor H. H. Turner, on "Astronomy." Professor E. H. Parker, three lectures on Impressions of Travel in China and the Far East; Professor William Stirling, six lectures on Physiology Subject; Dr. J. E. Marr, three lectures on the Influence of Geology on Scenery (The Tyndall Lectures); Rev. Canon Beeching, two lectures on Shakespeare; Mr. Benjamin Kidd, two lectures on the Significance of the Future in the Theory of Evolution; Mr. H. B. Irving, two lectures on the English Stage in the Eighteenth Century; Mr. Francis Darwin, three lectures on the Physiology of Plants; Professor B. Hopkinson, three lectures on Internal Combustion Engines (with experimental illustrations); Mr. J. E. C. Bodley, two lectures on the Church in France; Mr. J. W. Gordon, two lectures on Advances in Microscopy; Mr. M. H. Spielmann, two lectures on George Frederick Watts as a Portrait Painter; and Professor J. J. Thomson, six lectures on the Corpuscular Theory of Matter. The Friday evening meetings will commence on January 19, when Professor J. J. Thomson will deliver a discourse on Some Applications of the Theory of Electric Discharge to Spectroscopy. Succeeding discourses will probably be given by Professor S. P. Thompson, Mr. H. F. Newall, Mr. W. C. D. Whetham, Dr. R. Caton, Dr. Hutchison, Sir Andrew Noble, Bart., Professor P. Zeemann, Mr. W. B. Hardy, and other gentlemen.

From the report of the third competition and exhibition organised by the Association Belge de Photographie we learn that the fixture has proved very successful, work having been sent in from all parts of Europe. The only English worker whose name appears in the award list is Mr. F. J. Mortimer, who has gained the premier prize (silver-gilt medal) for his lantern slides.

MESSRS. HOUGHTON are publishing some new calendars for 1906, which are specially intended for the use of amateur photographers. These calendars are likely to be exceedingly popular as Christmas and New Year cards. A space is provided at the top for a photographic print, and the colouring and design is in good taste. The photographic application has been kept in mind, and soft, rich tints have been utilised with the design in a lighter shade of the same colour. Full particulars and an admirably illustrated booklet will be sent on application to 88-89, High Holborn, W.C.

THE South London Photographic Society.—This society's annual lantern lecture competition was decided at the last meeting, the medal going to Mr. F. W. Jeffery, who has thus won the competition two years in succession. Second and third positions fell to Mr. W. F. Slater, F.R.P.S. The judges, Messrs. J. M. Sellors and R. J. Terry, of the Croydon Camera Club, had to again complain that many competitors jeopardised their chances by including so many slides of an inferior quality.

THE scheme, put forward by the International Society, for erecting a public monument to Mr. Whistler, is chiefly to be welcomed because the work is to be entrusted to M. Rodin. A characteristic piece of work by a sculptor of his distinction would be, no doubt, an important addition to the monuments which are to be seen in London, and would have the greatest possible claim upon the attention of all intelligent art lovers.

SIR WILLIAM PREECE, K.C.B., F.R.S., will distribute the prizes and certificates at the annual prize distribution and students' conversazione to be held this evening (Friday), at the Northampton Institute, Clerkenwell, E.C. The conversazione for members and students will be continued to-morrow, December 9, when the building will be thrown open to the whole of the members and students and their friends.

Commercial & Legal Intelligence

ACTRESSES' Photographs.—An action was brought, in the King's Bench Division last week, by Mr. Alfred Ellis, of Baker Street, to recover damages for an infringement of the copyright in photographs of Miss Letty Lind and Miss Fay Davis, and for an injunction against Mr. Hearnden, proprietor of "The Gentleman's Journal," who purchased the blocks from the proprietors of the "St. James's Budget," and published reproductions in his issue. The defence was that the infringement was an innocent one, and defendant offered five guineas in settlement. The judge said he would accept defendant's undertaking to give up the blocks and copies, which was equivalent to granting an injunction. However, he would impose a penalty of one guinea on each of the two copies, and he assessed the damages at five guineas, and directed that each side should pay their own costs.

TRouble About a Photograph.—At the Greenwich County Court on Friday last, Thomas Kennett, of Vauxhall, sued Thomas K. Warhurst, of Ermine Road, Lewisham, for £2, or the return of a photograph of his father. This was handed to defendant to be copied and placed in a pendant, but he had not been able to recover it. He had taken proceedings at Westminster County Court

against a firm in the Strand to whom the defendant had sent the photograph to be copied, but the judge dismissed the case, telling him that Warhurst was the proper person to proceed against. Defendant did not appear, but it was stated on his behalf that owing to financial difficulties he had been unable to pay for the work. His Honour gave judgment for 1s., and ordered the return of the picture within a week.

EASTMAN Kodak Company of New Jersey.—In addition to the ordinary quarterly dividends of 1½ per cent. on the Preferred and 2½ per cent. on the Common Stock of this company, there will be paid on January 1 next an additional dividend of 2 per cent. on the Common Stock, making 12 per cent. paid during the past year.

PERSPECTIVE AND VIEW POINT.

To the Editors.

Gentlemen,—I have to thank you for the notice you gave last week of my book "Perspective Tables." That the subject I drew your attention to requires accentuation may be seen in a paper by Mr. Leisk, in your issue of to-day's date. While much that he says is interesting from a rule-of-thumb point of view, and so far as I know may be of use to many, some of his statements are certainly misleading.

One would imagine, for instance, from what he says, that every quarter-plate lens when used in a half-plate camera, would act as a wide angle lens, which is not the fact.

The statement, however, that attracted my attention most was "The shorter the focus of the lens the more violent will the perspective be," which is diametrically opposed to the real state of the case, as I stated last week. "From the same station point all lenses give the same perspective." When you alter your station point, of course the perspective is different, but you should not blame that on the lens. "The moral or lesson" Mr. Leisk goes on to say, "is that the lens whose focal length is nearest to the distance we hold a book from our eyes when reading is the one that will most truly render natural objects, as we see them." Now, any picture he may take, say with a 9in. or 14in. focus lens, may be taken with a 3in. lens of similar angle only smaller, and if it is good perspective in the one it will be good perspective in the other. So that what is called good perspective in a picture is more a conventional selection than anything else. His remarks as to looking at photographs through a lens of similar focus to that with which the photograph was taken are interesting, and the facts stated are made use of, as he says, in the stereoscope but his statements are incomplete from a scientific point of view for before distortion entirely disappears all the fundamental conditions of perspective projection have to be complied with. He only deals with one "distance" of the eye from the picture.

The subject may be of very little importance to the ordinary photographer who does his work only as he has been taught and who has no individuality, but difficulties are continually cropping up where a knowledge of this part of the subject is essential. Such as in the correction of perspective distortion by the lantern, the photographing of groups and figures to suit certain backgrounds, or the photographing of certain backgrounds to suit certain figures, etc., etc.

—Yours truly,
ROBT. F. SHERAR.

To the Editors.

Gentlemen,—With regard to your correspondent's letter in your issue of November 17, re "Makers' Formulæ," it may possibly be a help to him to know that the usual custom amongst photographic chemists in making up such formulæ is as follows:—Ounces of solids are taken as avoirdupois, i.e., 437.5 grains to the ounce; liquids ordered in ounces are measured, i.e., 480 minims to the ounce. When manufacturers wish to have the apothecaries' ounce they are usually careful to specify that, or as an alternative to order quantities in grains, which does away with any ambiguity. In the absence of any instructions to the contrary, it is usually safe to conclude that when ounces of solids are given in formulæ, they refer to the avoirdupois ounce (437.5 grains). ALFRED R. WHEATLEY, M.P.S.

22, High Street, Burton-on-Trent,
November 28, 1905.

THE FREE PORTRAIT SWINDLE.

To the Editors.

Gentlemen,—Thanks for your corroborative comments on Messrs. Brigham's action, re "The Free Portrait Swindle," at Scarborough, but please also read Hull for Scarborough, as the facts are as true of one town as the other.—Yours faithfully,

W. BARRY.

7 and 8, Park Street, Anlaby Road, Hull.
December 5, 1905.

DEVELOPING P.O.P.

To the Editors.

Gentlemen,—In reply to Mr. E. A. Bartlett's letter of inquiry respecting the development of faintly printed images on P.O.P. and P.O.P. postcards, I wish to give him a few hints, and to put him in the way of obtaining further information on the subject.

1st. The light for manipulation.—I have found from experience and experiment that the most important thing to attend to is the colour and power of the light in which the various operations must be conducted, in order to ensure perfect freedom from fog and stains, the former often being mistaken for the latter. It is almost impossible for anyone at first to realise how rapid P.O.P. really is until a developer of a suitable kind has been applied to it under favourable conditions. Then it is found that an image so faint as to be all but, if not quite, invisible to the eye before development can be developed into a strong image. This being the case, it is most important, and absolutely necessary, that all the operations (except the printing) connected with the P.O.P. be conducted in a room illuminated by an artificial light of a yellow colour; that produced by an ordinary paraffin candle, or of a paraffin lamp, without a yellow screen, is usually quite safe. But if one thickness of light yellow coloured tissue paper is placed in front of the light, perfect safety will be ensured for this purpose. If daylight must be used, the window should face the north, and must be glazed with yellow glass, or covered with canary fabric, in a similar manner to that adopted in a room suitable for working the wet collodion process in. But the former plan is recommended as being safer, because the source of light is much more uniform in power.

2nd. The printing.—This is best done by daylight (but any highly actinic artificial light can be used instead if desired or necessary), but the progress of the printing must be examined by a yellow artificial light only, otherwise fogged and useless prints will be the result. But if very dense negatives are to be printed from, or the daylight is very poor in actinic quality, as it usually is during very dark or foggy weather in the autumn and winter, it will be found convenient, if not advisable (although not absolutely necessary) to use a printing gauge or actinometer, which can be permanently attached to the printing

frame. As by ascertaining the number of tints necessary with each negative, and marking the latter with the number ascertained after the first satisfactory print has been obtained, it will not only be of present use, but will be useful in the future. It will only be necessary to know when the printing has proceeded far enough, which will save much time if many negatives are being printed from and several prints are required from each. Of course the number of tints necessary for the negative in the frame must be indicated outside on the front of the frame.

As the exposure required may vary from about one-fifth to one-twentieth (or even less than this) of the full "printing-out" time, the amount of printing necessary is not very exact in order to obtain satisfactory results. But of course printing time is saved if, as near as possible, say one-twentieth of the full "printing-out" time is given to each print instead of printing for a longer period, which, of course, is important if a large number of prints are required from certain negatives in as short a time as possible.

3rd. The developer.—I believe that almost every developing agent known may be employed with success after being rendered freely acidic. I have used hydroquinone, ortol, and pyro. with satisfactory results, but prefer the two latter, as they produce much more harmonious prints (i.e., they give more detail all over, and less blackness than hydroquinone does) and develop much faster. I can recommend the developer made from the following stock solution of pyro, viz.:—

STOCK SOLUTION.

Distilled, or other pure water, 5 ounces; metabisulphite of potash 1 to 2 drachms; pyrogallie acid (heavy crystals), 4 drachms. The quantity of metabisulphite of potash must not exceed two drachms, the development may be too slow.

To develop take:

Pure glycerine (or very thick gum arabic solution), 2-6 drachms pyro. solution (as above), 40 to 60 minims; water (boiled rain, tap, or well), to make 4 ounces.

This is the correct quantity to use in a half-plate glass or porcelain developing dish; if more is used the development will be slower, and stained prints more likely.

Immerse the dry print in the above developer, and quickly turn over and over to avoid air bells and other defects.

Only develop one print at a time unless several can be developed side by side, and then it is well not to do more than two. The development takes from about four to two minutes, as it becomes gradual quicker with each successive print, because the developer becomes richer in free silver which is added to it by each successive print.

The developer must be freely acid to blue litmus paper in order to work clean. It must also contain some gum arabic, fish glue, isinglass, or glycerine, in order to prevent the film or back of the print from being stained.

The proportion of either of the latter necessary will vary from about twice to six times as much as of the developing agent present in the developer. The above formula will serve as a guide, as different developing agents and formula may require more or less than that stated above.

The quicker the development is within reason the freer the prints are likely to be from stain, but if it takes place in less than one minute, it is very difficult to avoid over-development.

If the development is too slow, it may be caused by the developer being too weak generally, or it may be too acid, or too much gum, fish glue, or glycerine may have been added to it, or too much developing solution may be in use for the size of dish in use and the size of prints being developed. Or it may be due to there being too little free silver present in the developer, owing partly to the paper used only having a small quantity of silver present in it, or the developer

may have too much water in it, the latter being most probable. In the latter case the addition of a few drops of a 10 per cent. solution of nitrate of silver to it will increase the speed development.

4th. The stop bath.—A "stop bath" must be used, because it is impossible to stop the development quickly enough with water alone. The following is cheap and effective:—

STOP BATH.

Water 20 ounces.
Chloride of sodium (table salt)..... 2 to 4 ounces.

Immerse the developed print quickly in the "stop bath" and keep it moving for at least one minute, and let it remain in it for five or ten minutes longer. Then transfer it to a large dish of water, or, better still, to another "stop bath" half or a quarter the strength of the above "stop bath," in which it is allowed to remain until the whole batch of prints have been developed. It is then well washed in clean water before toning and fixing as usual. Always well rinse the fingers with clean water and wipe them dry after placing each print into the "stop bath" before proceeding to develop another print, otherwise finger-marks may be made on the prints.

As fuller working details, formulæ and other methods of working cannot very well be given in a letter owing to the space necessary, I must refer the reader to several very good articles on the subject which have appeared from time to time in the BRITISH JOURNAL OF PHOTOGRAPHY and elsewhere during the last few months, and from time to time for many years past also in the photographic annuals. The reader will also find much useful information on the subject in the "British Journal Photographic Almanac" for 1903, pp. 703 to 744, and to a letter which appeared in the BRITISH JOURNAL OF PHOTOGRAPHY for January 30, 1903, p. 98. The only thing I need say respecting the above article and letter is that since they were written I have found that boiled rain, well, or tap water, after being filtered, can be used for all the solutions with success, instead of the distilled water I recommended, as certain defects that I then thought were caused by the water I had used I afterwards found were due to other causes.

By both the methods indicated above, a reddish-coloured image is produced by development alone, which can be easily toned with gold, provided it has been well washed after the "stop baths" before toning. As I prefer to tone my prints with gold, I always use a developer that produces a reddish-coloured image, and have not tried to obtain a more or less pleasing tone by developing and fixing alone and I feel sure that the former plan of working is much easier and much more certain in action than the latter, because the correctness of the exposure is not so important when the former method is adopted. If the latter method is employed (i.e., developing and fixing alone), the use of an actinometer as a guide to the exact depth of printing necessary, in order to produce the tone desired, is almost indispensable.

The foregoing refers to the development of P.O.P. with an acid developer, which requires the presence of free silver. This is termed "physical development." But P.O.P. can be developed with a well-restrained alkaline developer if the prints are treated by a method previous to development, first introduced to the photographic public in 1893, full details of which are given by Mr. Wilson in a little book entitled "Paget Prize P.O.P., and How to Use It," to be obtained gratis from any photo dealer or from the Paget Prize Company, Ltd., Watford. No doubt one or the other of the methods indicated above will suit Mr. Bartlett, and perhaps some other readers of this journal. Thanking you in anticipation.—I am, Gentlemen, yours truly,

J. T. HACKETT.

3, Cherry Orchard Lane, Eastwood, Rochford, Essex,
November 30, 1905.

Answers to Correspondents.

*• All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

*• Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

*• Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

*• For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 1d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

F. C. Macmahon, 23, Academy Street, Inverness. Photograph of J. Stirling, Esq. of Farnham, Ross-shire.

P. Jones, 55, Victoria Street, Lincoln. Photograph of the Opening of the Lincoln Electric Tramway.

Mrs. E. Goodwin, 93, Church Road, Smethwick, Birmingham. Photograph, Old Chapel Farm, Smethwick.

DRAWING REGISTERED:—

S. Ashton, 91, Waterloo Street, Oldham. Drawing of St. Peter's Church Oldham.

RETOUCHING (A. E. Henson).—Your circle prints worked two years ago show very fair retouching in the fine-grain method; although the lines and shadows appear to have been unduly removed. You do not send prints before retouching, however, so it is difficult to judge exactly. Your present film may possibly affect rough matt papers in preference to glossy, and hence they desire greater breadth of treatment, and the only advice that seems sensible under the circumstances is—when in Rome do as the Romans do. A skilled retoucher should not be confined to one set or mechanical touch, but should be able to adapt himself to circumstances and the exigencies of the particular studio in which he finds employment. A coarse grain on heads of the size shown depends entirely upon subject and the printing paper used.

APPRENTICESHIP.—I herewith enclose my indenture of apprenticeship, wherein you will see I was to be instructed in the art, trade, or business of photography. I served my three years faithfully, but during my apprenticeship I was never allowed to do or instructed in retouching. My father wrote asking my employer to do so, but he said that was a different branch altogether, and did not come within my apprenticeship indenture, and, of course, I am greatly handicapped in obtaining a fairly remunerative berth, having to go as a printer only. Could you kindly inform me if I have good grounds of action against my late employer for breach of contract? You will see by my indenture I have been out of my time and away from my late employer about six months, as although he gave me a good reference as to my being a good printer and general assistant he only offered me 10s. per week, so my father refused to let me start for him, and I have applied for many situations, but not being able to retouch I suffer in consequence.—NEWCASTLE-ON-TYNE.

The "art, trade, or business of photography" is a wide term, and we should certainly say includes retouching, when the apprentice is bound to a portrait photographer. Retouching nowadays is really a very important part of the business. We

should say there is good ground of action for damages, but should suggest that the question be submitted to a solicitor. The indenture has been returned to you.

SOLAR PAPER.—I should consider it a favour if you would kindly inform me through the medium of your esteemed paper the formula for sensitising solar paper. The raw paper is, I believe, salted in the first place, then, when dry, it is sensitised and exposed while still wet. What I want to know is the method or formula used. This solar paper is very slow, and it requires an arc light for exposing.—**BROMO.**

A good formula for this will be found in the B. J. Almanac for 1906, p. 799. Immerse sheets of paper for 5 or 6 minutes in (1) silver nitrate, 150 grains; distilled water, 10 oz.; then hang up to dry. Then immerse in (2) potassium iodide, 500 grains; distilled water, 10 oz.; for five or six minutes and dry. After washing in clean water the paper can be dried by a gentle heat, and will keep for some time. For sensitising use equal quantities of (a) silver nitrate, 48 grains; distilled water, 1 ounce; (b) gallic acid sat. sol. Brush over the iodised paper, allow the coating to sink in, and then brush over again. Wash and dry. The developer is a saturated solution of gallic acid plus a little silver nitrate solution, and some acetic acid. If this works too hard use instead of No. 2 solution above the following: Potassium iodide, 240 grains; potassium bromide, 80 grains; distilled water, 10 oz., and add to A 2 or 3 grains of citric acid. After development wash well and fix in a 1 in 4 hypo solution as usual.

PROCESS.—We are not aware that Warnerke's tissue can now be obtained, but if anywhere it would be from Penrose and Co., 109, Farringdon Road, E.C., from whom also you would probably be able to get the photo-litho papers.

E. GOODWIN.—We have read through your rather long communication, but we are not clear as to the points you desire information upon. However, you, or the other photographer, have no copyright in any photographs you are paid for taking, unless the customer assigns it to you in writing. Therefore it would be useless to register it unless that has been done. The copyright in the painting belongs to the one for whom it was painted, unless the artist specially reserved it to himself by agreement. The search fee at Stationers' Hall is one shilling, but we do not undertake to make searches. If you send us two photographs of each subject, and one shilling and sevenpence for each we shall be pleased to effect the registration for you.

PLAIN PAPERS.—Can you through the medium of the B. J. give me a formula for sensitising plain drawing papers. I remember one in the Year Book of about 15 years ago. The paper was soaked in bichromate of potash and then sensitised. If you can give me particulars I shall be obliged.—**C. M. CLARK.**

A complete series of articles on plain salted papers appeared in our issues for April 28, May 12 and 19, and June 2 this year.

FERROUS OXALATE INTENSIFIER (J. B.).—Bleach in saturated solution mercuric chloride to which 20-50 minims hydrochloric acid has been added. After bleaching wash for about one hour. The negative is blackened by application of saturated solution of potass. oxalate, 6 parts by measure; saturated solution of ferrous sulphate, 1 part by measure. The ferrous sulphate being poured into the other. Well wash after complete intensification.

BROMIDE.—In your issue of B. J. of October 13, you give a pyro developer for bromide paper. (1) Is it any use for bromide postcards? (2) Is washing necessary between developing and fixing? (3) I want to enamel bromide postcards; what is the best to treat them with and when? (4) How much washing after fixing?

(1) Yes; but stains are more likely to make their appearance on the back of card. (2) Yes. (3) Squeegee them to talced plate glass, or ferrotype plate will give them the necessary high glaze. Squeegee them down after fixing, aluming and washing. (4) One hour's washing in several changes will be sufficient.

ENGLISH WEIGHTS.—Will you kindly oblige an old reader, who is not a chemist, by putting the following recipe into good old English? As it stands now it is not clear to a poor professional like myself:—Metol solution 1.10, 10 cc.; soda sulphite solution 1.5, 10 cc.; pot. bromide solution 1.10, 0.5 cc.; water, 200 cc.—**A. WHITELEY.**

Our correspondent should turn to the B. J. Almanac for 1906, p. 1081 et seq., where he will find the question of weights and measures clearly explained. Converting the formula into English measures, however, and assuming that the total bulk of developer is to be a pint, the formula reads, disregarding fractions:—Metol (dry), 44 grains; sodium sulphite (crystal), 88 grains; potassium bromide (dry), 2 grains; water to 20 ounces.

THE Second American Salon.—The British work has scored extremely well at the Second American Salon, for out of 100 pictures sent by 27 exhibitors, 67 pictures by 23 exhibitors have been accepted, and the jury of painters has selected "The Mother's Kiss," by Mrs. G. A. Barton, as the picture in the exhibition, and this will be purchased for the permanent collection of the Metropolitan Camera Club, at the handsome price of 100 dollars (£20). The third "honourable mention" in the exhibition was given to W. Clayden, of Plymouth, for his well-known picture "Tagging Home," while the first and second "honourable mentions" were also secured by non-Americans, going respectively to Guido Rey and to Alfredo Ornano, two of the Italian competitors. The pictures finally accepted for the American Salon are 221 from 81 American exhibitors, and 132 from 42 non-Americans. The latter include England, France, Germany, Italy, India, Holland, Spain, Austria, Ireland, Mexico, the Argentine Republic, and Cape Town.

SUNDERLAND Photographic Association.—Entry forms are now ready for the forthcoming exhibition of this society. Silver and bronze plaques (specially designed) are offered. The judges will be Messrs. Alex. Keighley, F.R.P.S., and Frank M. Sutcliffe. The Hon. Secretary is W. E. Kieffer, Stirling Street, Sunderland.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

The P.P.A. Assistants' Certificate. That the Committee of the Professional Photographers' Association are genuinely anxious to meet the wishes and requirements of assistants in the certificate scheme is undoubted. On the publication of the prospectus, just a year ago, it was announced that it was on trial and would be reconsidered in the light of experience at the end of the twelvemonth. In fulfilment of their promise, the Committee are now engaged in an investigation of the practical working of the scheme then devised, and have taken the judicious step of inquiring where the difficulty lies of those, who, from their having sent for the prospectus and not followed the matter up by applying for certificates, presumably, have some fault to find with the system. The brief report of the last meeting of the Committee, which appears in another column, shows that the opinions of those assistants who replied to the inquiry have been treated with the consideration that should be accorded them, and that the desire, throughout expressed, to benefit equally both employers and those they employ, is being acted up to. That such a comprehensive scheme as was attempted proves to be capable of improvement is not to the discredit of those who devised it, and it is to their credit that they have displayed the broadminded, and we may add, the benevolent spirit they have in dealing with the matter. Professional photographers and their assistants have more interests in common than either side appears to recognise, and if the Professional Photographers' Association is the means of causing the fact to be realised, assistants will have almost as much reason to bless its existence as that class on whose behalf it was primarily established.

* * *

Photographic Miniatures. In the early days of photography miniature painting was about at its zenith, and the old miniature painters obtained exceedingly high prices for their very beautiful portraits on ivory. Photo-

graphy, however, killed that class of work, and many of the artists were forced to take to colouring photographs for a livelihood, in which branch of work they produced much that was altogether admirable. At that period portrait jewellery, brooches, and lockets were very much in fashion, and it was the rule to see a fashionably dressed lady wearing a brooch or locket containing the portrait of some esteemed relative or friend in the form of a Daguerreotype, coloured paper picture, or even the humble glass positive. Fashions change, and for many years this class of jewellery was no longer seen. A few years ago miniature painting again came to the fore, and locket miniatures are now much in evidence. Many photographers, particularly those who were the first to take it up and make it a specialty, have found it a very profitable branch of business, but it may be doubted whether the high-class ivory miniature is destined to have a long reign. It is well-known, of course, that the best houses obtain large sums for a miniature in colours on a photographic base, and even photographers whose businesses are outside the circle of "society" can depend on not infrequent sales of miniatures at ten guineas apiece to the bourgeois ladies of Crouch End or Brixton. Yet fashion is a fickle jade, and a thing which is all the rage one season may be unheard of the next. It is conceivable that by its very popularity with other sections of society the miniature portrait at its best may fall into disrepute. We are not decrying the cheaper miniatures which are remarkable at the price and appear to satisfy quite fashionably dressed people, but it is highly probable that this vulgarising of the genuine miniature will prove its quietus until, in course of time, it comes out again. The other day, in passing through the West End, we heard a tout at a cheap photographer's calling out miniatures sixpence a dozen, and we are told that in the neighbourhood of Islington they are even being done at threepence the dozen. Be that as it may, we know that for some time past miniatures, tinted with aniline dyes, in an imitation gold locket, are being supplied from any portrait by stationers, drapers, and the like for something like a couple of shillings.

* * *

Stained Negatives and the Preventative.

Readers of our "Answers" columns have probably noticed that one of the most frequent queries concerns the removal of silver stains from negatives which have been printed from while they were damp, or which have been in contact with damp paper. The query is one more easily put than answered. Some stains are deeply seated; that is, if they are well in the film, for hypo left in the film adds to what would otherwise have been confined to a stain on the surface. Such stains are more difficult to remove, and in some cases cannot be removed. One is inclined to have but little sympathy with those who have valuable negatives ruined in this way, because the evil might have been avoided by the simple precaution of

varnishing. But varnishing negatives seems to be looked upon as a bugbear by the present-day photographer because it involves a slight—very slight—extra amount of trouble, which, under the most favourable circumstances, can be dispensed with with impunity. Collodion negatives had to be varnished—the film was too tender to dispense with protection—and hence varnishing was never regarded as an extra trouble. Nor can it well be so regarded nowadays, seeing the great immunity it confers upon a negative. Collodion negatives, stained in the printing, were things unknown, and so it would be with gelatine ones if they were protected with varnish.

* * *

Varnishing. While varnishing negatives is looked upon as a troublesome operation, it is, as a matter of fact, an exceedingly simple one. In the *ALMANAC* are several formulæ for negative varnishes, but few, we suspect, will care to make their own varnish. Some varnishes take several hours to dry, and have, to some persons, an unpleasant odour; others, on the contrary, dry at once and are comparatively free from smell. The question is which is the one to be used. Our preference is for a good spirit varnish with shellac as a base, i.e., the usual commercial spirit varnish. Some persons complain that spirit varnishes are difficult to apply and do not flow evenly over the plate, and therefore we may perhaps give a hint or two to those who use such a varnish for the first time. In the first place, the film should be made perfectly dry, as any moisture in it will tend to repel the varnish and prevent its flowing freely. If the moisture has been driven off before the fire the plate should be allowed to cool until it is nearly cold, or with just the chill off. The varnish is then poured on, flowed over the negative, and drained off into the bottle. The plate is then held in front of the fire and made quite as hot as the hand can well bear, keeping the plate in the position it was when the varnish was poured off. In five minutes, or when the plate is cold, it is ready for the printing frame. The great mistake of novices is in making the plate too hot in the first instance: the varnish does not then flow freely. The varnish may really be applied to the plate while it is perfectly cold if it be heated directly afterwards to prevent the varnish from "chilling." It may be mentioned the varnish does not flow quite freely over a gelatine film as it does over a collodion one, particularly if the plate is made very warm; but if the plate is cool at the time of application there is very little, if any, difference.

Finishing Prints with the Point.

* * *

We referred last week to the spotting of platinotype prints, our remarks being entirely in connection with the use of colour such as Chinese ink or charcoal grey applied with a sable brush. In some studios the spotting, and in some cases even more elaborate finishing, is done with a pencil. The objection to this method lies in the shine of blacklead which becomes prominent on a perfectly matt surface print. In the article we printed last week on matt collodion paper, Mr. Perkins recommended pencil for this type of paper, and if the lead matches the colour of the print, the spotting will be practically invisible on account of the equal semi-glaze of the print. We remember seeing some fifteen years ago a number of very finely finished cabinet platinotypes, the face being stippled in much the same way that a negative is retouched, and the backgrounds carefully worked in. The whole of the work was done with the point, a lead pencil being used, and the gloss of the work was very prominent. A couple of guineas for each print was the price asked and obtained, and, of course, at such a figure practi-

cally every print was framed, and under glass the shine of the pencil was not noticeable. A good deal of work may be done on larger prints and on enlargements with the carbon pencils which are supplied by artists' colourmen. The pencil is something between a crayon and an ordinary blacklead, and, while easy to use, leaves no shininess. In conjunction with the air brush such a pencil is very effective, the air brush being used for tones of some area, such as vignette backgrounds, strengthening masses of shadow and so on, while the point is employed for the sharper touches. Of course, for simple spotting and touching up platinotypes and bromides, a finely pointed carbon pencil may be used, keeping the point fine on the usual glass-paper pad, working on the print by fine stippling and carefully avoiding anything in the direction of a pencil mark which could be identified as a line. With extremely light, delicate prints, an H or HH retouching pencil may be employed with less danger of producing a hybrid effect.

Point Finishing—A Suggestion.

* * *

A modification, or, perhaps, an elaboration of the ordinary finishing with the point to which we have referred in the previous paragraph may be suggested, and, in the hands of a clever artist, should provide something in the way of a novelty. It is, frankly, a hybrid production, though the finished work may be very effective and successful commercially. An ordinary half-length portrait may be taken, and the whole of the figure stopped out on the back of the negative, so that when the print is made there is nothing but the head with, perhaps, the collar and tie, the rest of the paper being quite white. Either paper the same size or larger than the negative may be used. When dry the print will have the figure suggested by a sketchy line drawing, the work being finer and a little more filled in where the dress comes near to the head. A few touches will be necessary on hair, eyes, and so on to prevent the contrast between the photographic image and the sketched-in portion from being too marked. Of course platinotype and bromide are the most suitable processes, with carbon in cases where a print free from any glaze in the shadows can be obtained. If the newer glazeless tissues be employed, then carbon on a suitable single transfer paper might be used even with a fairly strong negative. Red chalk carbon would be very effective if the chalk used in finishing could be obtained of exactly the same colour as the carbon tissue. If the stopping out of the figure be done on the film side, and the principal lines are left, they will indicate the drawing and facilitate the hand-work. Care must be taken to cover the whole of the back of the negative, except the face, with two or three layers of tissue paper, so that these lines, suggesting the drawing of the figure, will only give the faintest indication on the print. The sketched-in portion would need to be done with accuracy of drawing and a certain amount of dash. Anything in the nature of a hesitating line would at once produce a feeble result.

A CAUTION.—We are asked to warn photographers against a woman of about fifty years of age, medium height, slender build, pale complexion, and dark brown hair, and generally of good address and appearance. She has been calling on photographers and picture dealers with two old-looking water-colour pictures, which she represents as the work of the late Peter de Wint, by whom they were left to her father. On a photographer in Scotland purchasing these for £2 10s., they were found to be copies and of no value. The woman sometimes sells through her daughter, a young woman wearing glasses, and at other times the "works of art" she has to dispose of are by David Cox and other artists.

THE WORD "PHOTOGRAPHY."

THE propagation of historical errors appears to be the self-assumed task to which the writer on photography in the "Daily Telegraph" is now applying all his powers, and for which he appears to be highly qualified. Much as we may regret the publicity which is thus granted to absolute misconceptions, we would ignore such lapses from accuracy did not the writer impute to others a like ignorance of the early literature of photography. What can one think of a writer who glibly puts aside the conclusions arrived at by such distinguished investigators as Dr. J. A. H. Murray and Major-General Waterhouse, and then proceeds to make statements which are simply naive admissions of unacquaintance with the best-known classics of photography? Thus in last Friday's "Telegraph" we are told that the paper which Niepce offered to the Royal Society in 1827 was long believed to be lost, and came to light in 1884. Does the writer know that it was printed in full in the "Literary Gazette" of 1839 (p. 138); that M. Biot was evidently acquainted with Niepce's work in 1839 ("Comptes Rendus, Vol. 8"); that Isidore Niepce, we believe, included the paper in his "Historique de la Découverte, improprement nommée daguerreotype," published in 1842? Historically its publication in these places is not of great importance, but the fact that our author pronounces it lost until 1884 is a disquieting commentary on his qualifications to discuss history with anybody moderately well read on the subject. The "Amateur Photographer" of Tuesday last, in the course of some lengthy notes on this same topic, omits to mention its confirmation of the canard (which first appeared in the "Telegraph") as to the alleged use of the word photography by Niepce in 1816. We are still without a shred of positive evidence that Niepce did use the word then or at all. The negative evidence, viz., Niepce's use of "heliography," in that last important document, his "Notice sur l'Héliographie," which he wrote four years before his death, is against the supposition.

Our contemporary, by way of "finally putting to rest" the question as to whether the word photography was used earlier than in Herschel's paper of March 14, 1839, refers to Dr. Meme's translation of Daguerre's "Historique et Description des Procédés du Daguerreotype et du Diorama," in which the translator explains (in a footnote) that the word "photographic" is used by him in preference to "photogenic" as more exactly translating the French "photographique." But the argument ignores the date of the French original, viz., June 30, 1839, by which time—three months after Herschel's paper—the word had commenced to become current. It leaves us still without one solitary instance of the word "photography," "photograph," or "photographic" ante-dating Herschel, and merely amounts to throwing dust in the eyes of those who might take the matter up.

We are told that Arago's reference (again on June 30) to the partnership between Niepce and Daguerre disposes of Dr. Murray's contention that the use of photography and the allied words goes back no further than Herschel. But have our "historians" compared the vital passage (as translated by Memes) with the French original? We will put the two side by side for them:—

Meme's (p. 13): . . . The original (Daguerre's "Of producing images with "Historique," p. 14): . . .
 sixty or eighty times greater . . . "de reproduire
 rapidly than the earlier les images avec soixante
 applications of the photo-ou quatre-vingts fois de
 graphic principle." promptitude, que les
 procédés anciens."

The italics are ours. Into the passages to which Dr.

Murray's critics attach such precious importance, the word "photographic" is introduced by the translator!

The crucifixion of fallacies is a thankless task, and we would not dwell at such length on the false issues which have been raised in the present etymological enquiry were we not desirous of recording the plain facts in such a way that any student of photographic history who may wish to lend Dr. Murray his aid may not be misled by speculations which have the one prominent merit that they draw attention away from an egregious historical error.

PRINTING PROCESSES.

XVI.—GASLIGHT PAPERS.

THERE can be no doubt that "gaslight" papers are coming more and more into favour as their good qualities are more appreciated. The ease, too, with which warm tones can be obtained by mere prolongation of the exposure and dilution of the developer has caused them to be received with favour by amateur workers.

As is probably well-known, the emulsion used for these papers is a chloro-bromide, that it to say, a mixture of chloride and bromide of silver, and to this must be ascribed the ease with which warm tones can be obtained, and also the slowness of the papers. It is impossible to state definitely the speed, but using a graded negative, it was found necessary to give from thirty to thirty-six times the exposure required for an average make of bromide paper. There are, of course, as with bromide papers, various kinds of "gaslight" papers, and each must be tested for its own speed and gradation.

Gaslight papers have long been credited with a somewhat short scale of gradation, and it is generally assumed that they are certainly prone to blocking up in the shadows. Whilst this is true to some extent, so much depends upon the exposure and development that it is unsafe to dogmatise, for we have found that some papers will give, with correct exposure and not too prolonged development, a scale of gradation from bare glass to an H. and D. density of 2.0, within which will lie the densities of the average negative.

It is an open question as to the best method of developing these papers, but from a series of tests which we have carried out we have come to the conclusion that a full exposure and a very brief development with a strong developer will give the longest scale of gradation with the most satisfactory colour of image: that is if black is aimed at.

It may be asked why one should use gaslight papers to obtain black images when equally good results can be obtained on bromide paper with greater ease and less expenditure of time. But this very fault, the necessarily long exposure, is one of the strongest arguments in favour of gaslight papers. If, for instance, it is desired to turn out a large number of prints from some half-dozen or a dozen negatives, one can actually get through the work with greater expedition and certainty by using gaslight paper than with bromide, unless a rapid printing machine is available.

In a case, such as we have just outlined, the method which we have seen most successfully worked is to use a number of printing frames, and place them on a table or bench underneath a Wenham gaslight or inverted incandescent burner. To these lights the exposure is not inordinately long. In another case in which only the incandescent electric light was available, the printing frames were placed on a bench in two or three rows, and the lamp set swinging in an ellipse over the same. Whilst we had very grave doubts as to the results, these were put at

rest when the prints were developed. When a large number of prints are required of one subject, it would naturally be necessary to make a series of duplicate negatives, and thus ensure that all had the same density, when the question of correct exposure would be at once solved: this being the only difficulty when different negatives are used.

Gaslight papers, of course, have received their name from the fact that they can be manipulated in gaslight, that is without any dark room, but whilst it may be necessary to work them in actinic light occasionally, for turning them out in quantities, it is certainly advisable to use some non-actinic medium in the dark room lantern; for this enables one to work with greater freedom and with a total absence of fog. The colour of the medium, however, can be very light, either a very pale yellow, or simply a piece of matt opal, or one of the pleasantest lights of all is that given by light chromium green glass. Both these will give a brilliant illumination all over the room, and yet be perfectly safe, even when the most sensitive of these papers is worked close to the lamp.

As regards the developer, the favourite seems to be the well-known combination of metol and hydroquinone, and it certainly works satisfactorily in most cases. Working out all the formulæ to grains per ounces, the following appears to be the mean:—

Metol	0.8 grains.
Hydroquinone	3.0 grains.
Sodium sulphite	24.0 grains.
Sodium carbonate	36.0 grains.
Potassium bromide	0.3 grains.
Water	1 ounce.

Making up a developer on these lines we have found that it will suit every make of paper, though some require a slight increase of the bromide. It gives a pure black and white image, which has no tinge of rustiness, and it is rapid in its action. If development is prolonged the shadows will readily block up, thus giving one more contrast if this is desirable. Some operators prefer to so adjust their exposure to the developer that the print can lie in the same until finished. When working in quantities this course is no doubt satisfactory, but even then we prefer to give such a generous exposure that the print must be removed very quickly from the developer, before development ceases—in fact, as we have found that in working by this method a much longer scale of gradation is obtained, there is less blocking up of the shadows and absolutely no tendency to fogged or stained edges—a fault which prolonged or forced development is very apt to cause.

To arrest development some use an acid bath, but we think it preferable to wash the print at once in plenty of water, and use a fairly strong running stream. This may be more trouble, but we have found even when the prints are thus washed for five minutes that there is no increase in density, that is development does not continue, and there is far less likelihood of stains in fixing.

Stains during fixation are one of the chief bugbears of gaslight papers. They are invariably caused by allowing the prints to lie one over the other, particularly when not thoroughly freed from all traces of developer. If an acid fixing bath be used, and if the prints are thoroughly well washed prior to immersion in the same, and then kept well under the surface of the fixing bath and constantly on the move, there is very little chance of brown or yellow stains.

Before considering the question of warm tones we may possibly give the following developer as typical of those which will give the blue-black print which is occa-

sionally preferred to the pure black, particularly with glossy surfaced papers:—

Sodium sulphite	50 grains.
Amidol	5 grains.
Potassium bromide	1.5 grains.
Water	1 ounce.

This must be made up within two or three days of use, as it will not keep well.

To obtain warm tones with gaslight papers it is only necessary to increase the exposure and dilute the developer, or one may do both the above and add ammonium bromide and carbonate. In the ALMANAC for this year, pp. 822-5, will be found various methods of obtaining warm tones. Using the above mixture of metol and hydroquinone and diluting one part with 19 parts of water, one can obtain any tone from black to red chalk by practically increasing the exposure in geometrical ratio.

It will occasionally be found that gaslight papers, particularly the glossy varieties show when finished certain streaks and marks, which look very much like pencil scratches. These are due to abrasion of the surface, and whilst it is not quite clear why they should arise—for bromide prints are certainly not so prone to them—they can in almost all cases be removed by rubbing them with a pledget of cotton wool wetted with spirit. If this fails to remove them, then they should be gently rubbed with the following:—

Thiocarbamide	5 grains.
Nitric acid	5 minims.
Methylated spirit	$\frac{1}{2}$ ounce.
Water	$\frac{1}{2}$ ounce.

Care must be taken, however, when using this as it is a fairly energetic reducer. The best way is to lay the print face up on a sheet of glass, then to gently rub the spots or marks with a bit of cotton wool damped with the above solution, and immediately to plunge under a stream of water, continuing the rubbing and alternately washing and applying the solution until the marks disappear. This solution will also remove developer or fixation stains.

There is possibly only one other point upon which we need touch, and that is as to the stability of the warm-toned prints. Some years ago it was advanced that the warm tones obtained on lantern plates by increase of exposure and modification of the developer were not stable. This has also been supported by Bakelandt as regards gaslight papers, but we cannot see how this can be upheld, particularly, if as stated, it is supposed that the image consists of silver *plus* organic matter, for we cannot see where the organic matter is to come from.

It is well known that on pure chloride of silver films, with increased exposure and modification of even ferrous oxalate developer, warm tones can be obtained, and some such images we now have which, so far as one can judge, still show all their original vigour although twenty years old. If this be so, we cannot quite see why the introduction of a little silver bromide into the film should produce an image which is other than pure silver. It is far more likely that the silver is deposited in a much finer physical condition, and thus gives rise to warm tones.

There is another point, which, however, has nothing whatever to do with the chemical constitution of the image or its stability; it is one purely of photographic ethics. Can a gaslight print be called a bromide? We must confess that we are not quite sure how to answer this question. "The custom of the trade," which is a recognised legal argument, is that a "bromide" is a print prepared on bromide of silver paper. If a photographer

were to receive an order for a certain number of bromide prints and be supplied prints on gaslight paper, could the customer, if he became aware of the fact, refuse acceptance of goods or claim damage for substitution of an inferior article? This is one of those delicate questions on which we think to quote a learned judge in a famous case "expert

evidence must always be received with caution; whilst I have no intention of impugning either the veracity on honesty of the witnesses that we have to-day heard, I feel that they have done their best to complicate matters, and you, gentlemen of the jury, had better reject the whole of their evidence and use your common sense."

THE WEEK IN HISTORY.

Claudet's Patents.

THE early experimenters were assiduous patentees, and if all the things for which protection was granted them were still private property, the art of photography would be very strictly limited. For example, in the year 1841, Claudet, on December 18, obtained protection for a number of improvements which we rightly regard as the property of everyone at the present time. One is for "performing all the operations upon the plates (Daguerreotype) which were formerly carried on in the dark, in a room lighted through the media of various colours, such as red, orange, green, or yellow, but red, I prefer, which, having little effect upon the plates covered with the sensitive coating, allows the operator to see how to perform the work without being obliged as before to remain in a dark-room."

Claudet, also, in this same patent, describes the often patented and advocated scheme of developing the exposed plate in situ in the camera.

Further, it is curious to find him patenting the photographic background:—"A third feature of my improvements consists in applying to portraits taken by the Daguerreotype process painted backgrounds or scenes, representing objects which, by the various distances of their parts, could not otherwise be correctly introduced in a Daguerreotype portrait on account of the different foci of the several objects."

The Great Photographic Lawsuit of 1854.

On Monday, December 18, 1854, commenced the hearing of the celebrated case of Talbot v. Laroche in the Court of Common Pleas. The action was brought by Fox Talbot against Mr. Laroche on the ground that the working of the collodion process was an infringement of his (Talbot's) patents in calotype. Talbot, no doubt, was himself convinced that he was morally entitled to benefit from a process which certainly owed something to his researches but had completely supplanted his calotype process. However, the case was notable in the number of leading characters in photography who figured in it, but chiefly for the light which it throws on some dark places of photographic history. In particular, on the relative shares of Reade and Talbot in the invention of photography. It has been argued that the Rev. J. B. Reade was the discoverer of the development of a latent image, and that Talbot had got the idea from him. But in the scanty literature relating to Reade

there is nothing to show that such is the case, and the facts of the case appear to be as stated by Reade during his cross-examination in Talbot v. Laroche. He said: "He washed paper with solution of common salt, then with nitrate of silver, and that he placed it before the solar microscope to receive the picture, and he washed it with an infusion of galls, and proceeded to take the picture. He found it necessary to keep the paper wet, and in order to see how the picture was being developed, though he had no idea of an absolutely invisible image, but in order to strengthen the image which had been produced, he put his head in the microscope and watched how the picture was being developed, and when it had come to a certain tone of blackness, which he termed solar mezzotinto, he suspended the operation and fixed by hyposulphite of soda; and that he had, on one occasion, been called away, and at that time a piece of paper had only been a short space of time under the action of light, but when he came back he found an image on it. This, however, did not give him the idea of a latent image, and he had not the slightest notion of it until he learned it from Mr. Talbot."

Talbot, of course, lost his action, and the collodion process was thereby relieved from the attacks which threatened to extinguish it.

Fox Talbot's Patenting.

Fox Talbot, too, patented almost every one of his discoveries, and on December 19, 1849, he was actively engaged in depositing at Southampton Buildings the specification of a number of improvements. Among these was the use of porcelain as a support of the photographic image, the use of varnished paper as a substitute for glass, and a curious method of obtaining more complete fixation of photographic prints on paper. "For this purpose, the picture, after undergoing the usual fixing process, is dipped into a boiling solution of strong caustic potash, which changes the tint of the picture, and, usually, after a certain time, induces something of a greenish tint, which we consider a sign that the process is terminated."

In his next sentence Talbot anticipates, in a measure, the current processes of "sulphide" toning. "The picture," he adds, "is then well washed and dried, and if the tint required by it is not pleasing to the eye, a short exposure of it to the vapours of sulphuretted hydrogen restores an agreeable brown and sepia tint."

HISTORICS.

THE PRACTICE OF THREE-COLOUR WORK.

II.

AN ideal panchromatic sensitiser for trichromatic work must sensitise equally and vigorously, for green, yellow, orange, and the actual red. We have already seen that ethyl red does but badly satisfied these requirements, that pinachrom is far superior, but is not quite perfect. Finally, pinacyanol cannot be considered as a panchromatic sensitiser. Mixtures of different dyes have up to the present not proved satisfactory.

We consider, that if not absolutely impossible, it is at least improbable, that one dye will be found which will combine all the above qualities.

Those who want a sensitiser for as far into the red as possible, must use three separate plates for his negatives. If a Lumière "Blue label" plate be exposed behind the blue filter, a plate sensitised with pinachrom behind the green filter, and a plate of the same kind sensitised with pinacyanol behind the red filter, the gradation, and therefore the character, of the negatives will be the same throughout.

A new and extraordinary red sensitiser has been called by the Höchst dye-works, dicyanine. Plates sensitised with this greenish blue dye show in a spectrogram a maximum between

A and B, and work extraordinarily cleanly. But in spite of this sensitiveness extending into the extreme red, the dicyanine plates require behind the red filter a considerably longer exposure than pinachrom or pinacyanol plates, which is plainly shown by the spectrograms herewith. For practical three-colour work dicyanine will be of little value, but very valuable for scientific spectrophotography.

sufficient density is always obtained with ease; the dark summer green acts too slightly on the plate, so that this colour may easily be represented by a dirty brown. This defect can be obviated to a great extent by so damping the blue and yellow of the green filter that it will require a long exposure. But this, however, has its limits, for if the green filter is made darker, the green itself will be weakened, and even with longer

Exposures for the Green.

We have already seen above that the green filter exposures are the longest, and that also the best green sensitisers, such as ethyl red, orthochrom, and pinachrom leave something to be wished for in the green sensitiveness. In the yellow-green

exposure there is no better density in the green. When photographing dark green leaves, especially shiny ones, it frequently happens that they appear equally dense on all three negatives. This is not the fault of the filters, but is caused rather by the fact that we have only photographed the white light reflected

from these leaves, and this white light will, with correct exposure, naturally act equally on all three plates.

Light Tints.

The reproduction of light tints by trichromatic work offers many difficulties. In every case very exact work and an accurate estimation of the exposures is necessary to reproduce bright-coloured tones correctly. Let us take, for example, a very bright blue. Such a colour consists of a little blue mixed with much white. The bright blue must, if it is to appear in the prints in the correct tone, act through the green and blue filters like white, but slightly weaker through the red filter. If the exposure through the red filter is too long, white will frequently not be differentiated from the bright blue in the negative. Another difficult colour is a light neutral grey, that is, black diluted with more or less white. Our eyes are very sensitive to very faint differences in shades of grey, and it requires an accurate agreement of the constituent images to reproduce this colour quite correctly.

The three fundamental colours used for pinatype give, when correctly-mixed, an absolutely pure grey, so that it appears as well rendered as all the other compound colours, because the colours in a pinatype print do not lie one on top of the other, as in other three-colour pictures, but are combined in a very thin film of gelatine.

Often enough our colour prints show impossible greens, violets, and other tones. We will not further advance the contention that these tones actually occur, but are not recognised by us. It is more correct and laudable to call them

faults which are still adherent to colour photography, and to try and improve them by working in common.

Explanations of the Chart and Spectrum Tests.

The plates to be compared were simultaneously exposed behind the same red filter, and then developed and printed.

Figs. 1 and 2.—The plates sensitised with ethyl red reproduce the red strips very badly. The top strip of the colour chart, which is a reddish violet and obviously contains besides the blue red of tolerably small wave-length, appears as black on the ethyl-red plate, but as a half-tone on the pinachrom and pinacyanol plates.

Fig. 3.—The superiority of pinacyanol as a red sensitiser is distinctly shown in the lowest deep red strip and the top reddish violet one.

Fig. 4.—Dicyanine, which from its spectrogram should be the best red sensitiser, is for practical three-colour work less useful than pinacyanol, as its sensitiveness leaves something to be desired. At the same time Figs. 1 and 2 distinctly mark the difference between this dye and ethyl red.

The spectrograms were taken with a diffraction spectroscope by gaslight. The datum lines are the line of lithium between B and C, the yellow D of sodium, and the β line of potassium in the blue. The exposures were as 1 : 2. In taking the dicyanine spectrogram the position of the camera as regards the grating had to be altered in order to include the extreme red of the spectrum on the plate. This explains the shift of the K β line towards the D line.

Dr. E. KÖNIG.

[For the blocks illustrating this article we are indebted to our contemporary, "Photographische Mitteilungen."]

MORE LETTERS TO A MIDDLE-CLASS PROFESSIONAL.

DEAR J.,—It is getting rather late to write you about Christmas work, but photographers are as fond of procrastination as the public, and probably your Christmas rush will not commence until shortly before the day, and will doubtless continue up to within a few hours of the midnight chimes of Christmas Eve. We have had people come in at four o'clock on the day before Christmas Eve and want a dozen carbons for presents next day. You can't oblige them at that, but, doubtless, you can in other ways, and I am writing you to ask if you are making the most of your opportunities, and to point a few of them out to you. If you have already made your arrangements all well and good. Christmas is a regular institution, and you will, perhaps, remember to get ready early next year.

I suppose you will have already got your specimen Christmas cards out, and, perhaps, a neat circular announcing that you make them, for as yet the public are in many instances unaware that we make these cards.

Anyway, they should be reminded, for we ought to have two weeks clear for getting them off when the state of the light is considered.

At the same time you should take the opportunity of emphasising the value and appropriateness of photographs as Christmas presents. Laying great stress on the very personal nature of such a gift, and its power of recalling, and recalling in a favourable manner, the donor.

The new private cards, with space for photograph, cannot be too highly commended, and all photographers should get a specimen book. It is the private card that in the past has been the unconquerable rival of the photographic card. Now we can combine the two photographic private cards should begin to go with vigour.

In my last letter to you I had something to say about mounting; the same rules with regard to harmony and contrast apply equally to Christmas cards.

Therefore, mount your prints on suitable colours. Warm tones on warm tones and black prints on greys.

The ordinary cards are all very well in their way, of course, but why not have your own special design? They will attract attention and custom. It is easy to make a border negative of design, and a mask for negative, so that portrait is printed with plain paper surround. The border negative, with opaque patch corresponding to shape of portrait, is placed in register, and printed on the aforementioned surround. Two registering guides on mask for portrait negative and two on design negative are all that are required. Carbon or artificial light papers, with no visible image before development, can be printed as easily as P.O.P.

The design should embody the date, and some seasonable wish. A fancy design should be worked in also. Any black and white artist will draw this for you for a few shillings. The finished prints may be mounted on your ordinary mounts.

I am working an idea of my own just now; valuable, since it combines the Christmas greetings with the photograph, and yet the photograph can later be used as a print of the ordinary description. This is done by having the folders printed with a Christmas design and wishes.

Our local printer did it from his stock blocks, and charged me very little. After Christmas, of course, the folder has only to be removed to leave the plain mount and print. We make no extra charge for this, and as a consequence our orders for photographs as Christmas presents are largely increased, and many which would have had the ordinary cards now pay for cabinets, for a small extra cost we tie up in silk ribbon. This greatly adds to the effect. The ribbon is exactly the same colour as folder.

Beside the special folder and cabinet we are making as a speciality, and at a further small cost, a photographic inset for folder in the shape of a four-leaf sheet printed on two pages. This is, a leaf folded

in the middle is printed from the sitter's negative on one side and on the other from a special negative made from a design in Indian ink on white card. One design is a black and white drawing of a snow scene, with the usual greeting, but more usually we make a special design and negative for each client. The design in this case is merely "A Merry Christmas" in fancy lettering, whilst below is the sitter's ordinary signature. When we cannot obtain this we stick a visiting card on to the card bearing the other lettering.

Are you doing anything in Christmas postcards? As we do not see the force of doing a cabinet-size picture at a ridiculously low rate, we are not. If, however, you get the chance of doing a hundred or so they are worth it. In this case either get the commercial card with inscription printed on address side of card, or put whatever wording you require on the film in reversed lettering.

An almost unexploited field is the production of almanacs. This is surprising, when one considers that nearly all fancy almanacs have pictures of some description upon them. How well some of your best specimens would take their place.

Why do not photographers make an almanac for their own advertisement? A really artistic production could be done at a cheap rate, and would not be confounded with the monstrosities of the grocer. A taking child study would be just the thing, and if really good, the calendar would obtain a place on a wall and be a standing advertisement for the next twelve months.

The best method of making almanacs, either for this purpose or for clients, is to get an ordinary white plate-marked mount with wide margins and get the printer to put the months and days round the plate-mark. If this is not done too stiffly, and if the printing is forceful, the effect is good.

For one of our clients we have a good order for a calendar, made as follows:—Three different positions were selected of the whole-plate size. These are dry mounted on to 14 x 11 rough white imitation hand-made paper mounts. On each mount four mounts are printed, and the three mounts making the complete twelve months, with the three different positions upon them, are tied with silk cord.

Even simpler than the former idea is to get a number of date pads from the stationer, the cost being merely nominal. These pads are then stuck on the foot of the ordinary mounts either with adhesive or a couple of brass paper fasteners.

If further elaboration is wanted, anyone who can write a fair hand can easily write greetings, mottoes, or any special wording on the mount in fancy inks. Many colours can now be obtained, as well as gold and silver inks made by Rowney.

Well, as it is so near Christmas, and you will practically have no time to carry out these ideas this year, I say no more.—Yours,

STUDIOSUS.

A CHARGE OF VULGARITY.

MR. JUSTICE BUCKLEY having recently from the Bench commented on what he calls "the offensive vulgarity of the present day in using photographs of people—even on postcards," Mr. Louis Langfier, of Langfier, Ltd., Old Bond Street, makes a lengthy reply in the London "Evening News" of Monday last. We may quote the major portion of the article, in which Mr. Langfier makes a strong claim for the recognition of the photographer as an artist:—

Vulgarity, it has been stated, has defamed the photographic art, and the picture postcard and the illustrated weekly have worked the ruin—so some would have us believe—of a once honourable, although modern, profession. Never, to my mind, have more unjust and undeserved aspersions been cast on a business in which there is a high standard of professional conduct and honour. On behalf of the photographic world I desire to uphold the reputation of our profession, and to show how ill-judged are such general comments as are made without a full knowledge of the facts. I can, with authority, as representative of the opinions of the leading photographers, emphatically disclaim any insinuations that vulgarity has vanquished art in our business.

Never, at any time, has Art (with a capital A) played such a prominent part in our professional methods, and without a good claim to being "an artist and a gentleman" no West-End photographer could possibly hope to succeed. There is no taint of vulgarity on our business, for if there were we should instantly lose the support of our clients who look for refinement and artistic effect—and not in vain.

Photography has, in my opinion, not only removed itself far above any suspicion of vulgarity, but it has proved the chief means of popularising art. Modern methods and up-to-date processes have enabled the masses to obtain the most beautiful and artistic pictures and portraits they have ever had.

Artistic Revival.

It is to the photographic picture postcard, circulated in countless millions at popular prices, that much of the prevailing high taste is due. These have educated the masses in art, and fed the

flame of artistic revival. If it were not for the illustrated papers and picture postcards many celebrities of the State, Society, or the stage would be unknown to and unrecognised by the public—a loss that the ordinary man would most certainly deplore. To carry the matter to a higher and more artistic plane, it is only necessary to remember that many of the masterpieces of the great painters, Rembrandt, Vandyck, and others, with most of the pictures in the Louvre, would be almost unknown to the public if it were not for their photographic reproductions on postcards and elsewhere. In the name of my profession, I take grave objection to the allegations of "offensive vulgarity," and contend that, on the contrary, much has been done by the chief photographic artists and the rank and file to elevate art once again on her pedestal in the sight of all men. When it is said that to reproduce a picture "without permission" is "vulgar" the true state of affairs must first be known. Many ladies of title, and others whose portraits are in great demand, are given complimentary sittings by the chief photographers on the understanding that the copyright of the photograph in question for purposes of reproduction and illustration belongs to the artist. Lady So-and-So and the Marchioness of Such-and-Such, with the clever or beautiful Miss "Leading Light," are thus able to obtain the most artistic results possible free of any charge, and the public gets the very latest and best pictures at the cheapest possible rate. This arrangement has been found to be to the satisfaction of all parties in the past, and to call it "vulgar," in theory or practice, would seem to me inaccurate and absurd. In the great majority of cases, of course, this is done with the full knowledge and consent of the ladies and gentlemen concerned, and in nearly every case it pleases the photographed person immensely. At one time or another the majority of our aristocrats have been photographed in this way, and knowing that full justice will be done them in the matter of obtaining an artistic likeness, they have expressed the liveliest satisfaction at the method and its harvest of popularity.

General Election Cards.

The only occasions on which there is the slightest grumbling is when by some mischance "a bad print" obscures the beauty of some fair and not unvain sitter, and only then. No respectable high-class photographer would ever utilise a photograph which a sitter had ordered and paid for unless he felt satisfied that by so doing he was acting with the permission and approval of his client. It is self-evident that no photographer would run the risk of involving himself in vexatious litigation and the certainty of losing some of his best sitters for the sake of the half a guinea or a guinea he would obtain for its reproduction in a paper or on a card. It is only, of course, the photographers of the highest class

who would have the opportunity of obtaining the clients whose portraits are in public demand, and these naturally always seek to act in the best interests of their clients. Of the value of picture postcards the forthcoming general election will prove an eloquent testimony. By the thousand portrait cards will be sent out to their constituents by the Parliamentary candidates, and the utility of, and high place held by, photography will be once again exemplified. In my profession, more perhaps than in any other, we are advancing fast. The wheels of progress have carried the camera to a point where it is the most exact and satisfying of all the arts. The fact that we have "studios" is not our only claim to be considered artists first and photographers afterwards.

BACKGROUND HANGING.

THE hanging of background is a somewhat important matter and should receive more than cursory attention, more especially from the owners of small studios. Backgrounds have a knack of being decidedly in the way in anything but a very large gallery, and frequently the operator, rather than move chairs and tables, and do athletic feats with 8 by 8 cameras, prefers to dump all sitters in front of one background, thus spoiling his own work, and giving an appearance of sameness to all the photographs turned out.

FIG. 1

Without a doubt, the best means of mounting a background is on a stretcher, this keeping the canvas absolutely taut, and without the annoying creases common to other methods, which cause so much trouble when working up prints. They suffer, however, from the disadvantage of requiring much space to turn grounds and stock them, but being undoubtedly the best method we must discuss them.

The stretcher to take ground need not be weighty: a skeleton frame of 3 by 1 stuff is right. The corners should be absolutely at right angles and firmly joined. When stretching background, place one tack in the centre at top and bottom, and then work from these tacks outwards to the ends, stretching ground. Meanwhile, before getting quite to the corners, place tacks centrally at the sides, and work outwards from them, leaving corners until the last. If there are any well-defined straight lines in the background, say, in an architectural subject, see that they are not screwed or leaning. With very thin stuff for the background base, it is as well to tack through small squares of card, thus preventing tears, or to run tape round the edges. With paper grounds, the edge of stretcher should be well covered with glue, the ground placed on, and allowed to dry. If the centre now sags, it is only necessary to very slightly damp the back with an almost dry sponge.

Large 8 ft. by 8 ft. stretchers, for convenience in moving, may be provided with two feet, complete with two castors, the whole being so arranged that the bottom stretcher is only about $\frac{1}{2}$ of an inch from the floor. The feet may well be of 3 by 3 stuff, and project 8 inches each side of ground, this being ample width of base.

With this type of stand it is usual to place a ground on each side. The only drawback is the amount of moving required to

FIG. 2

get out a ground wanted, if there happens to be two or three others in front of it.

A very excellent idea used in a well-known Northern studio is to have all the stretchers made quite uniform and perfectly rectangular. Into the bottom bar two small wheels are sunk. The backgrounds are now placed in shallow grooves, quite at the side of the studio and parallel to the end wall, the grooves being about 4 feet longer than the stretchers, when the latter are pushed home. When a ground is wanted, it is only necessary to pull it from amidst the other ones out into the studio, the extra 4 feet of groove being sufficient to hold the frame upright. Of course, only one ground can be mounted on a frame. The one disadvantage to this system is that it is not possible to use the background diagonally, or to shift its position to any great extent. But we think that this does not amount to much, since these big grounds are usually used for full-length figures. The small head-grounds can be on a different system. Those who have a wide enough studio cannot do better than use this system, as, for

perfect stretching and ease of access to all grounds, it is unsurpassed, 10 seconds sufficing to push back ground not wanted, and to pull out fresh one.

The small head grounds, mentioned above, are apt to get in the way if left lying about, or piled up against the wall.

A new stand, of my own design, may be of interest, since it is for grounds on stretchers—most of the commercial apparatus being for grounds on rollers. The chief advantage is that it can be so constructed that eight or more grounds only take up the space of one stretcher on feet.

To begin with, all the frames must be of an exact size. The side-pieces are then divided exactly into two halves. At this point a hole is to be bored, and a round pin let in exactly at right angles to the side of stretcher, and projecting about 2 inches.

A stand is now to be made with two uprights, which may be of any height, joined with two crossbars of such a width that the two uprights are kept slightly more apart than the width of the stretchers. These two uprights should be supplied with feet and castors, but as the whole complement of background will be heavy, a large base is advisable.

On the uprights, on the inner side, facing one another, and at an equal height to their fellows, place transversely two, three, or any number of pairs of arms, noting only that the lowest arm is of such a height that when the background frame is hung between on the pins the bottom shall just miss the ground. The others may be at any varying distance required—three we find enough, giving three different heights for ground.

It will be seen also that either end of background can be used with equal facility, and there can be a ground on each side of frame. Our first support was made like the stand of a cheval glass, so that the background could be swung at an angle, but we found this of doubtful advantage.

The supporting arms may be of any convenient length, but must be shorter than the feet. There should be two, four, or six U-shaped slots in these arms to take the pegs in background frame, an equal number on each side of the stand, and as close as the width of the frames will allow.

You now see that any number of stretchers can be hung on this frame out of the way, and that it is quite an easy matter to get at any ground wanted. Moreover, the stand is easily placed in any required position.

So much for stretchers. The only other practical method of hanging is on rollers. There are two roller systems, one resembling an ordinary roller-blind, the other rolling from the bottom.

Of the two the last is far preferable, the former method always allowing the ground to crease, at least, a little.

However, the blind system may be preferred by some, and we will discuss the chief points to be noted.

The roller on which the ground is to be packed should be of a good diameter, say, 3 inches, and quite parallel to the floor at the required height. The background must be now fixed to this so that the top edge is quite straight, not spiral, and so that when unrolled the side of ground is quite at right angles to the roller. This is a ticklish matter, but freedom from creases depends almost entirely upon it.

The background-maker will usually pencil a line on ground where it should be tacked, and with a little ingenuity, a pencil and the skirting board, a line may be made on the roller in the correct position for the line of tacks. By far the best method of fixing ground to roller is not to tack, but to get a joiner to make a groove in the roller to fit into it a loose tongue, which will be so flush as to appear to be part of roller. To fix ground,

lay it over this roller (after taking out tongue), put in two or three tacks to get roller in correct position, and then laying cloth over groove, hammer in the loose piece of wood. The ground should be now firmly fixed, but capable of easy removal.

It has been thought that to get ground free from creases, the bottom roller, lath, or bar, should be heavy. Such is not the case, however. We have tried an iron rod of $\frac{1}{2}$ inch diameter with lamentable results, the ground being one mass of creases. The reason is that the bar, like all iron rods, was flexible and gave in the centre, breaking the inviolable rule, that to prevent sagging the bottom bar must be absolutely straight, with no warp or sag of any description—straight as a billiard cue, in fact. If this is borne in mind, an ordinary inch or inch and a half wood roller is as good as anything for the bottom of the ground. The rolling system is usually that of the endless cord.

By far the best roller method, however, is the theatrical system, the curtain rolling from the bottom.

Here the top of ground is tacked on to a flat, stiff board, taking care to get the line of tacks at right angles to the sides of ground. The bottom is fixed to a roller, a foot longer at each end than the background, and taking the same care to get it at right angles to the side and parallel to the top board. The roller should be about 2 inches in diameter. The only difficulty is to explain the cording of this system; it is perfectly easy when you are fitting it up, but intricate to explain. Take two separate pieces of thick picture cord, one twice the length, and the other three times the length of background. Obtain a single block pulley wheel and a double block wheel (i.e., two separate and distinct wheels in one fitting), and screw on to the top board of ground, an inch or two further apart than the width of ground. Now, for ease in fitting, put board in place with ground hanging down. Now take the longest piece of cord and fasten the end with a tack on to the free end of roller, which is just below the single wheel and on the opposite side to the cleats upon which the cords are to be fixed when the grounds are rolled away. Now make about a dozen turns on the roller, away from you (it is always an easy matter to give more if that is not enough to roll ground properly), and now pass the end of cord through the single pulley, take along the board, pass through the double block, and down to cleat. Now do the same with the other cord, but pass through the free wheel of double block only, and down to cleat. It is now best to join the two cords.

If all this has been done properly, when the double cord is pulled it will be found that the bottom rolls turns round and winds up the background as far as the board.

The only objection to this method is the quantity of cord left over when the grounds are rolled up. But if large cleats are fixed at side of grounds, this can easily be kept out of the way, preserving the qualities of compactness and easiness of access that makes the blind system the only possible one in some studios. We have tried both roller methods, however, and find the bottom roller one by far the best; in fact, if care is used in the rolling up, it is little short of the stretcher method for lack of creases. One of the disadvantages of this system, however, has been the fact that a foreground could not be used in one piece with background.

We have got over this difficulty, however, in the following way:—

A large roller was obtained with two instead of only one groove—half an inch separating them. It is almost impossible, by the way, to use this method without using this type of roller, tacking being so liable to screw. The background and foreground combined was fixed to the board, with the wheels attached, as before

explained, and allowed to hang loose. The roller, with tongues removed, was now laid on the background with the ends $\frac{1}{4}$ of an inch above the floor. The tongue was placed *behind* ground, and forced into the top groove, leaving the unoccupied groove open and in front of ground. The extension piece now comes from behind the roller. Now place the second tongue *underneath* the extension and force in groove, tightening the material round the roller. If the roller is now wound with cord, as in the ordinary way, the extension piece and background will roll up together. It is necessary, however, to keep the extension piece free from creases, as the marks will be communicated to background.

One of the best features of the roller system is the ease with which any number of grounds can be hung in a small space, whichever method of roller you use. It is best to have a wide, flat board, or boards, fixed in the studio at the requisite height from the floor and parallel to it. This board should be levelled with a level. On to this can now be screwed the bearings for the ordinary rollers to revolve in, fresh bearings being put a few inches further out as required.

If, however, the other system is used, some method of fixing the flat boards at the required height is necessary. They can either be screwed onto the top board with angle pieces or placed in the angle pieces.

W. FOSTER BRIGHAM.

SELECT METHODS IN LANTERN SLIDE MAKING.

[An Article by A. J. Jarman in the "Camera and Dark-Room."]

ONE branch of the photographic art that interests the amateur at this time of the year particularly is the making of transparencies for use in the lantern, especially if the pictures so made are from choice negatives that the amateur has produced during a summer visit to some interesting place, or during the summer recreation.

It will not matter whether the views are made upon plates or films, or whether they are 5 x 4 or 7 x 5; there is sure to be some suitable little spot upon such negatives where a picture can be obtained by contact with a good quality lantern plate. It may so happen that in a 7 x 5 negative there is a rustic bridge, with a running stream beneath, perhaps the tail-race of a rustic wheel, with a few bushes near; if so, that will be just the kind of view that will produce an excellent transparency.

Sometimes it is found that among many of the 5 x 4 negatives that we made on our outing in the country, or maybe in the street of a village, that there are some that possess the right quality for lantern slide making, and that the whole of the space is not required. All that will be necessary in such a case will be to place the sensitive plate so as to cover the desired view. Now, a careful slide maker always backs his plates. It is only when a backing is used that is in optical contact with the glass that crisp positives or negatives can be produced. If backing the plate is too much trouble, then place the negative and plate in a printing frame backed with a piece of dead black paper previous to making the exposure. This prevents, to some extent, the effect of halation, which at all times gives the effect of a blurred image.

As to the best kind of lantern plate to use it is difficult to state, because all of the makes of such plates to-day are good. Plates for such work are made now whereby they can be printed from the negative like printing out paper, and simply toned and fixed. The best advice that can be given here is for the amateur to take a certain kind of plate and adhere to the method of working, until he is master of the right exposure and developing. If it is desirable to be successful, thoroughly successful, do not try every kind of developer that is advised; learn to make up your own developer, become master of it; there will be found then no difficulty in making a good and successful lantern plate.

Lantern-plate Developers.

The formulae here given can be relied upon for giving good and satisfactory results, and should the resultant transparency sometimes be a little hard, or too contrasty, it can be reduced to the right density with advantage. In the first place, see that the dishes and trays to be used for transparency work are thoroughly clean; make up a new fixing bath as here given; be sure there is no stray light in the dark-room during all the operations, then

there will be no fear of fogging, the shadows will always be clean. Should the desire be that the whole of a view must be shown upon the slide, then there will be no alternative but to make a transparency by reduction by use of a camera and lens. For simple working there is no better plan than selecting a suitable part of the negatives as described.

Procure several clean glass bottles of about twenty-ounce capacity, fitted with clean corks; provide also a large bottle of distilled water, for the reason that more failures are due to the use of impure water than from many other sources. Dissolve in the following order in one of the bottles:—

1—Metol	30 grs.
Warm distilled water	16 ozs.
Hydroquinone	30 grs.
Pure sulphite of soda	$\frac{1}{2}$ oz.

Add the sulphite after the metol and hydroquinone are dissolved; now make up a solution of carbonate of soda, also mixed with distilled water—

2—Pure carbonate of soda	1 oz.
Distilled water	8 ozs.
3—Potassium bromide	$\frac{1}{2}$ oz.
Pure water	6 ozs.

The fixing bath must be made up and kept for use in a separate vessel after mixing; any sediment should be allowed to subside, retaining that which is clean and clear, pure.

Fixing Bath.

Warm water	24 ozs.
Sodium hyposulphite	$\frac{1}{2}$ pound.
Sulphite of soda	120 grs.

Stir well as soon as dissolved; add the following mixture made up or

Warm water	8 ozs.
Chrome alum (commercial)	$\frac{1}{2}$ oz.

Add this to the hypo solution, mix thoroughly with a strip of glass. The resultant clear solution is ready for use.

The following is also an excellent developer for lantern plates, but works more slowly. A rich warm black tone is obtained by its use. Make up the following:—

1—Warm distilled water	10 ozs.
Hydroquinone	180 grs.
C. P. sulphite of soda	2 ozs.
Potassium bromide	10 grs.
Sulphuric acid	10 drops

As soon as the mixture is well incorporated, add another six ounces of distilled water.

2—Carbonate of soda (crystals)	1 oz.
Carbonate of potash	1 oz.
Water	16 ozs.

The necessary solutions now being made up, take the negative from which the transparency is to be made, place it in an ordinary printing frame and repair to the dark-room. Open the box of lantern plates it is intended to use, brush the face of the negative with a clean, flat, camel's hair brush, and the plate as well. Adjust the plate upon that part of the negative it is intended to reproduce. Place over it a piece of black paper, press the backboard into position, and hitch the spring tight. Now make the exposure to a good source of light, such as a full gas jet of about sixteen candle-power; make the test by giving, say, four or five seconds at two feet from the light. Having made the exposure, take of the No. 1 developing formula, two ounces, No. 2 soda solution two ounces, add a few drops of No. 3 (the bromide solution), or, in place of the bromide solution, use four drops of citric acid to one ounce of water, rock the tray so as to mix the contents, then insert the exposed plate; rock the tray gently; in a few seconds the image will appear, and in the course of half a minute to one minute the development will be complete. Wash the plate well under the faucet, then place in the fixing bath, and allow the plate to remain some time longer in this bath than is necessary to dissolve or clear out the creamy portion of the plate. As soon as this is complete, wash the plate well for half an hour, then wipe the surface over very lightly with a tuft of wet absorbent cotton while the water is still running upon it; then place in a rack to dry.

To use the hydroquinone developer, expose the plate in the same manner as for the metol combined developer, only the exposure must be longer—from eight to ten seconds. The development will be a little slower. Take No. 1 two ounces by measure and one and one-half ounces of No. 2. If the image should develop at a slightly rapid rate, due to the negative being held too close to the light, or because the negative is very clear in the shadows, a few drops of the bromide solution must be added to the developer. This will assist slightly in retarding the development, but if the image develops up with good contrast, continue development until complete. If more plates are to be developed, start them in this developer without the addition of fresh solution; in fact, it is at all times a good plan to start the development of a plate in the developer that has been previously used. This plan will save many a plate, especially if the exposure has been a little too long; then, if necessary, a second tray containing fresh developer can be used to bring up the image to full density.

Collodion Emulsion.

The description given is only for the making of lantern slides by contact and development, but there are other ways of making lantern slides. One method is to produce them by reduction in the camera, the other is to print them out by a direct printing process, either by the carbon process or by the use of a simple collodion emulsion. To enter into the carbon process here would occupy too much space, but for the benefit of those amateurs who care to make their own plates the following simple and certain formula is given. In the first place, provide half-a-dozen amber-coloured six-ounce glass bottles, clean them out well, dry them, and fit a new cork to each. Prepare the following:—

1—Nitrate of silver	120 grs.
Distilled water	2 drs.

This mixture is best made in a small chemical flask, so that the dissolving may be aided by heat. Add two drachms of pure alcohol; when all the silver nitrate is dissolved it will be ready for use.

2—Chloride of strontium	64 grs.
Pure alcohol	2 ozs.
3—Citric acid	64 grs.
Pure alcohol	2 ozs.

Obtain six ounces of plain collodion from the stock dealers; take two ounces of this, add thereto thirty drops of No. 1, shake the mixture, then add one drachm of No. 2, a few drops at a time, shaking the mixture occasionally; then add half a drachm of No. 3. Give the bottle containing this a good shaking. The mixture will be ready for use within half an hour.

Clean a dozen cut lantern slide plates with a mixture of alcohol one part, strong water ammonia one part, water four parts. Polish the glass well with a new chamois leather, brush around the edges of the plates for about one-eighth of an inch a weak solution of albumen—the white of one egg to eight ounces of water; when dry, coat the plates with the collodio-chloride of silver by pouring a small pool of it upon the centre of the plate, allowing it to run to each corner by tilting the plate, then drain the excess from one corner into the bottle it was poured from, taking care to rock the plate backwards and forwards, so as to prevent the collodion running in streaks. In the course of five minutes the plate will be dry.

Coating with Emulsion.

It is needless to say that the operation of coating and drying of these plates must be carried on in a safe light, not necessarily ruby; a gas jet will do, with a sheet of orange paper placed in front just to screen the direct rays of the jet from illuminating the plate. As soon as the plate or plates are dry, place one upon the negative in just the same way as already described; then place the negative and plate in the sunlight or good, bright daylight; fit the back of the printing frame so that when the back half is opened about half of the transparency plate can be seen from the back. Continue the printing until the shadows appear to be bronzed in, then remove the plate and proceed to wash and tone it just the same way as for any printing out paper. Fix in plain hyposulphite of soda solution, one ounce to thirty of water. Wash the plate well in a tray by changing the water occasionally for half a dozen times. Do not wipe this plate; the films will be too delicate. Simply place it in a rack to dry, and, when dry, mount it in just the same manner as described. Be sure the water is free from dirt. By tying over the nozzle of the faucet a piece of cheesecloth in which a tuft of absorbent cotton has been placed, this will filter out any dirt that the water may contain. The collodio-albumen process is out of date to-day, but there has never been a process that surpassed this plan of making transparencies. Every quality desired in a transparency is obtained; as to lasting quality, they appear to be as permanent as the glass upon which they are made.

CATALOGUES AND TRADE NOTICES.

An attractive price list has been issued by Messrs. Elliott and Sons, containing full particulars of the range of photographic specialties made by the famous Barnet house. The booklet is designed by Mr. Charles E. Dawson, and is quite in that artist's happiest vein.

New Christmas postcards from Messrs. Griffin.—Messrs. J. J. Griffin, of 20-26, Sardinia Street, have put on the market a new line in Christmas bromide and P.O.P. postcards that are embellished with some attractive designs. They are being issued at popular prices, and are of the well-known quality associated with the firm's productions.

CHRISTMAS postcards in Barnet P.O.P., gaslight, bromide, and self-toning paper reach us from Messrs. Elliott and Sons, Ltd., who have enlisted the services of Mr. Charles E. Dawson in the ornamentation of the address side, with the result that selection can be made from half a dozen designs which are quite a refreshing variant on the style of embellishment commonly adopted.

Photo-Mechanical Notes.

The Etching of Labels.

A CORRESPONDENT from Birmingham sends us a neat metal label in which the bright letters stand out in relief on a dark ground, and asks us how this is done. In the first place, a negative must be made of the lettering or design (unless it happens to be the same size, when it may be printed direct on to the metal with suitable ink). This negative must not be reversed. Then a piece of sheet metal, which may be either zinc, brass, or copper is taken of suitable size, and the surface polished with fine pumice powder. It is now flowed over with sensitive solution as in ordinary zincographic printing, dried, and the negative brought into contact with this, film to film, and printed either by daylight or the arc lamp. The plate is then rolled up with stiff transfer ink and developed in cold water. After drying and dusting with bitumen or dragon's blood the plate is etched, nitric acid and water being used for zinc, and a solution of perchloride of iron for brass or copper. If greater depth is required than can be obtained in one etching, then it is recommended to protect the sides by means of dragon's blood, dusted on four ways (i.e., the American powder process of line etching), as this will afford sharper sides than the English "rolling-up" method. When the etching is complete the resist is cleaned off by means of lye and turpentine, the ground blackened, in the case of zinc by flowing over sulphate of iron solution, in the case of brass and copper by means recently given in this paper, and the surface of the design polished with fine charcoal, when the lettering will stand out brightly in relief.

Mercury Vapour-Lamps in "Process."

THE L.C.C. School of Photo-Engraving and Lithography has recently had installed a pair of Cooper-Hewitt mercury-vapour lamps designed for process work. These have been tested by students against a pair of "Westminster" enclosed arc lamps. Firstly, a careful and accurate test was made of the current consumed by an independent electrical engineer. He stated that two arc lamps took 14 ampères, while the two vapour lamps took $3\frac{1}{2}$ ampères. The voltage was 200, direct current. The students making the tests were not informed of this until afterwards. A glossy bromide print having had graded exposures going from black to white was then pinned on the board, and one half covered with black velvet. A plate was coated with Mawson's collodion, and sensitised in an 8 per cent. silver bath; exposure was then made with one pair of lamps; these were then switched out, the velvet was then transferred from the one half of the graded original to the other, and the other pair of lamps switched on and exposure made. By this device both exposures were on the same plate, and therefore had the same sort of film and afterwards the same development. The result proved to be that the mercury-vapour-lamps required more than three and a half times the exposure of the arcs, and the exposures were repeated several times, both for short and long times, and all gave the same result. There is no doubt that in this case there is practically the same cost of current for the same effect produced—that is to say, the vapour-lamps take only one quarter the amount of current that the arc lamps take, but they take about four times as long to do the work, though for certain originals they can be very conveniently used, and they may be safely placed closer to the originals than arc lamps, which makes them a little more economical, but against this must be set the much heavier initial cost of the mercury lamps, and their more expensive up-keep.

A. J. NEWTON.

Printing from Intaglio Plates.

According to a patent (No. 28,392) of Sir Joseph Wilson Swan and Mr. Donald Cameron-Swan, a photo-engraved intaglio plate is

printed in the lithographic manner by a method such as the following:—

A sheet of prepared lithographic zinc is coated with bichromated albumen, gum, gelatine or other sensitised medium. When the coating is dry the plate is exposed to light under a half-tone positive made as described in patent No. 28,392, 1904. After exposure it is rolled up with lithographic ink, developed in cold water, gummed up, allowed to dry, then damped and rolled up with stiff lithographic ink, and dusted with bitumen, dragon's blood, French chalk, or other similar or suitable powder.

The plate is then etched with dilute nitric acid to a sufficient depth, washed in water and dried, and the whole surface washed clean with turpentine. The plate is now in intaglio, the hollows being clean zinc whilst the surface retains its coating of albumen.

Bitumen, resin, or other similar and suitable powder is next dusted over the whole plate so as to fill up the hollows caused by the etching, and the surplus is wiped off the surface, and the plate heated sufficiently just to melt the bitumen or other powder. The plate is then placed in a bath of dilute caustic potash so as to remove the albumen film from the surface whilst leaving the bitumen or other powder in the etched parts. The surface now being clean zinc, it is gummed up, the gum adhering to the surface but not to the hollows filled with bitumen or other powder.

The gum is allowed to dry, and the plate is immersed in benzole, turpentine, or other suitable solvent of the bitumen or other powder, so that it is completely dissolved, and the hollows left clean. Lithographic transfer ink is then dabbed into the etched intaglio portions of the plate, the surface washed with gum and water, and the plate is ready for rolling up with a lithographic roller, when it is printed in the usual manner of lithographic printing, either on a hand lithographic press, or on a lithographic machine having a flat or curved printing surface.

In printing, the hollow recesses of the plate receive the ink, and the surface of the plate is kept clean by the repulsion of the greasy ink by its periodic damping with water, glycerine and water, or such similar or usual methods.

Instead of using metal for our plates, lithographic or other similar or suitable stone, or any substance possessing the special properties necessary for lithographic printing may be used.

On Thursday, December 7, Mr. R. Busch lectured at the London County Council School of Photo-Engraving and Lithography on "The History of Colour Printing in England." He traced the steps in colour printing from the time of rubricating with red down to the elaborate methods of this and the last century, and illustrated his remarks by a collection of books and prints probably unequalled outside the British Museum.

THE Nottingham Camera Club Exhibition will be held on March 14 to 17, when handsome bronze plaques of special design will be offered for competition. The Ilkeston Exhibition closes on March 5, and arrangements have been made for sending exhibits on to Nottingham, free of cost to exhibitors, and afterwards to the Leicester Exhibition, which opens on March 24. Prospectus and entry forms may be had on application to the secretary, S. W. Barlow Vines, Market Chambers, South Parade, Nottingham.

THE Berlin Photographic Exhibition of 1906.—The fine prospectus of this exhibition, in course of organisation by the Verein zur Förderung der Photographie for July next reaches us from the secretary, Paul Hanneke, 41, Bamberger Strasse, Berlin, W.50. As we have already announced, the exhibition will include all departments of photography—scientific and pictorial, applied photography and "process" processes, colour photography, and exhibits of the trade.

Exhibitions.

THE AMERICAN SALON.

THE second American Salon is now open in New York, and the following list of exhibitors and recipients of awards appears in the issue of "The Photographer" just to hand, from which journal also we glean some particulars of the exhibition. The Jury of Artists have made the following awards:—

\$100 Purchase Prize of the American Federation for the Best Picture, Second American Salon.—Mrs. G. A. Barton, Birmingham, England, "The Mother's Kiss"; 1st hon. mention: Guido Rey, Turin, Italy, "Scene Antique"; 2nd hon. mention: Alfred Ornano, Genoa, Italy, "M. Maeterlinck la Mort de Tintagiles, Act IV."; 3rd hon. mention: William Clayden, Plymouth, England, "Tugging Home"; hon. mention: Louis Fleckenstein, Faribault, Minn., "The Lily Pond"; hon. mention: Frederick Haven Pratt, Worcester, Mass., "Study of a Face."

\$50 Award by "The Country Calendar" for Best Landscape (American Work).—James E. Underhill, Brooklyn, N.Y., "Against Storm and Tide"; hon. mention: Frederick Haven Pratt, Worcester, Mass., "Landscape, Northern Italy."

\$50 Award by the Landmark Publishing Company for Historical Landmark.—Geo. T. Power, Chicago, Ill., "Niagara Falls."

The British exhibitors were Mrs. G. A. Barton, Lionel C. Bennett, Henry W. Bennett, A. H. Blake, Rev. H. C. Campion, William Clayden, Tulloch Cheyne, J. Page Croft, E. D. Taylor, Charles F. Grindrod, W. A. I. Hensler, E. O. Hoppe, S. G. Kimber, C. J. King, W. Harold Lane, G. Edgar Lee, Lewis Lloyd, R. B. Lodge, Ernest Marriage, J. C. S. Mummery, W. H. Nithsdale, and Marian Silverston, not a particularly representative list of pictorial photography in this country.

There were 340 pictures accepted, by 123 exhibitors, 81 American, and 42 from England, Italy, Argentine Republic, Cape Town, India, Holland, Spain, Mexico, Ireland, Germany, and Austria, making quite an international affair. The American workers are credited with 2.65 pictures apiece, and the foreigners with 3.16 apiece. There were some further pictures from abroad, which, however, did not get through the Customs House in time. Guido Rey and Alfredo Ornano, both of Italy, had the largest exhibit, with nine each; Curtis Bell, Louis Fleckenstein, and C. E. Townsend, all three Americans, follow with eight each; Rudolf Eicke-meyer, the Misses Parrish, J. H. Field, Vivian Burnett, Mrs. G. A. Barton, and Marian Silverston, of England, and Giuseppe Castrocio, of Italy, have seven each; and the remainder from one to six apiece.

THE "ZIGO" EXHIBITION.

MESSRS. ILLINGWORTH AND Co. are to be commended on their enterprise in demonstrating to a discerning public the good qualities of "Zigo" paper by an exhibition of the prize prints entered in the recent "Zigo" competition.

At Anderton's Hotel, Fleet Street, where the exhibition was held last week, a collection of prints was shown, remarkable not so much for their pictorial excellence, although in many cases pictorial qualities were conspicuous, but for technical attributes that proved beyond question the extent of the range of colours obtained by the simple manipulations necessary for producing "Zigo" prints. The procedure for the production of these prints is probably known to every one of our readers. Simple fixing in the ordinary "hypo" baths of varying strengths, coupled with printing to various depths, gives all that the most exacting P.O.P. printer can require.

In the present show we were particularly impressed by the fact

that the claims made for "Zigo" were substantially proved by the users of the paper in the competition itself, and the most varied and excellent effects appear to have been obtained with the greatest ease.

In each competition set, three prints were entered, and in nearly every case they demonstrate a range of tones obtained by the specified means, almost startling. No. 1 may be a rich Bartolozzi red, No. 2 a sepia, and No. 3 almost black. In one instance a perfect black has been obtained, by extreme over-printing and prolonged fixation. In any case the results obtained must be very gratifying to Messrs. Illingworth, and there is no doubt that this exhibition of "Zigo" prints will assist in making the paper even more popular than it is at present. During the exhibition practical demonstrations of the process were given, and no doubt the visitors quickly grasped how little there was to learn in order to produce the varied results shown on the walls.

OXFORD CAMERA CLUB.

At the members' exhibition of the Oxford Camera Club, held last week, a system was adopted which may be found of advantage by other societies. Out of the number of prints submitted (253 altogether), 213 were hung. Mr. H. Snowden Ward acted for the society as a one-man selection committee, and by him the pictures were divided into three classes: the first class were marked with a red disc, the second with a small piece of white paper in the shape of a fan, while the third were not marked at all. In the first class 47 pictures were placed, in the second 53, and in the third 113. In carrying out this task Mr. Ward bore in mind, in the first place, the general standard of the exhibition, and, secondly, the individual standard of each exhibitor. Thus prints were rejected from the collection of a strong worker which would have been accepted from a worker whose whole results showed less ability. No rigid lines were drawn, and consequently no strong worker was bound of necessity to have all his pictures accepted, and the rejections not only went towards the strengthening of the exhibition, but also tended towards the strengthening of the individual exhibit. Beside the forty pictures rejected, some eighteen works of a technical character were placed in a class by themselves. These included two colour pictures by Miss Acland, Mrs. Baker's plant studies, Mr. A. H. Hannis' wonderfully fine studies of protective mimicry, Mr. W. L. G. Bennett's panorama, and, to some extent, Mrs. Veley's animal studies.

Mr. Snowden Ward addressed a meeting of the members on the merits and demerits of the pictures, and in the course of what was necessarily somewhat detailed criticism took occasion to remind his hearers that people talked a good deal about the limitations of photography. When they did that he always changed the subject to something totally different. They knew something about the limitations of photographers, but they knew nothing whatever about the limitations of photography. No one had reached them; no one had approached them. He urged his conviction, however, that there were some four to six members represented in that exhibition who, if they would give to photography the same amount of attention that many men gave to golf and many women to fancy needlework, and would give that attention earnestly and seriously for five years, would in that time be among the very first photographers in the world.

A CENTRAL Amateur Photographic Club.—We are informed that a proposal is on foot to establish a club for amateur photographers near Charing Cross, where will be available a studio, dark-rooms, and printing rooms, etc. The premises are those of the Glass Photographic Studios, Limited, and the services of the staff of this firm are to be at the disposal of members. Those interested in the scheme may hear particulars from Mr. A. R. F. Evershed, 15, Great Winchester Street, Old Broad Street, E.C.

FORTHCOMING EXHIBITIONS.

December 12-20.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 5, Pembroke Road, Portsmouth.

December-January.—Wishaw Ph. A. Hon. Secretary, Robert Telfer, 138, Glasgow Road, Wishaw.

January, 1906.—Shettleston Camera Club. Hon. Secretary, Wm. Kitson, Hawthorne Villa, Shettleston.

January, 1906.—The Dover Institute Photographic Society. Hon. Secretary, H. Plowright, 47, Maison Dieu Road, Dover.

January, 1906.—Brierley Hill Camera Club. Hon. Secretary, J. Thomas, William Street, Brierley Hill.

January 11-13, 1906.—Boston Camera Club. Hon. Secretaries, H. M. Hames and R. W. Halliday, 65, West Street, Boston.

January 13-February 3, 1906.—The Third Scottish National Salon at Dundee. Hon. Secretary, V. C. Baird, Broughty Ferry. Entries close December 30, 1905.

January 25-27, 1906.—South Essex Camera Club. Hon. Secretary, Thomas Michell, 180, Browning Road, Manor Park, E.

January 31, 1906.—Tring Camera Club. Hon. Secretary, J. Owen Raymond, Frogmore Road, Tring.

February, 1906.—Windsor Camera Club. Hon. Secretary, Thomas J. Cartland, Thames Side, Windsor.

February, 1906.—Cardiff Windsor A.P.S. Hon. Secretary, W. A. Woodward, 187, Mackintosh Place, Cardiff.

February-March, 1906.—Birmingham Photographic Society. Hon. Secretary, Lewis Lloyd, Norwich Union Chambers, Congreve Street, Birmingham.

February 3-10.—Cape Town Photographic Society International Exhibition. Entries close January 13, 1906.

February 3-February 25, 1906.—Marseilles Fourth International Salon. M. Astrer, Sec. Gen., 11, Rue de la Grande-Armée, Marseilles.

February 6-9, 1906.—Guisbrough Fine Art and Industrial Society. Hon. Secretary, George Page, 34, Westgate, Guisbrough, Yorks.

February 13-27, 1906.—Greenock C.C. Hon. Secretary, W. D. Boyd, 2, Church Place, Greenock.

February 20-21, 1906.—Royal Albert Institute, Windsor. J. W. Gooch, Hon. Secretary.

Feb. 22-24, 1906.—Bowes Park and District. Hon. Sec., H. C. Bird, 91, Whittington Road, Bowes Park, N.

February 24—March 10, 1906.—Edinburgh Photographic Society. Hon. Secretary, J. S. McCulloch, 3A, N. St. David Street, Edinburgh.

March, 1906.—Larkhall C.C. Hon. Secretary, Robert Rodger, 26, McNeill Street, Larkhall.

March, 1906.—Leicester and Leicestershire Photographic Society. Hon. Sec., W. B. Woodland, 18, Beckingham Road, Leicester.

March, 1906.—Rugby Photographic Society. Hon. Secretary, R. N. Myers, 13, Bridget Street, Rugby.

March, 1906.—Photographic Society of Ireland. Hon. Secretary, H. V. Yeo, 194, Clonliffe Road, Drumcondra, Dublin.

March, 1906.—St. Helens Camera Club. Hon. Secretary, John Glover, 14, Ormskirk Street, St. Helens.

March 3-10, 1906.—South London Photographic Society. Hon. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

March 6-20, 1906.—Glasgow Southern P.A. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

March 7-8, 1906.—Doncaster Camera Club. Hon. Secretary, T. Haigh Connor, 39, Market Place, Doncaster.

March 12-15, 1906.—Cripplegate Photographic Society.—Secretary, Fred. Leeks, 8, Barford Street, Islington, N.

March 13-14, 1906.—G.E.R. Mechanics' Institute (Stratford). Hon. Secretary, A. Woolford, 16, Grove Green Road, Leytonstone, E.

March 14-17, 1906.—Nottingham Camera Club. Hon. Secretary, S. W. Barlow Yines, Market Chambers, South Parade, Nottingham.

March 19-24, 1906.—Sunderland Photographic Association. Hon. Sec., William E. Kieffer, Stirling Street, Sunderland.

April, 1906.—Barrhead Amateur Art Club. Hon. Secretary, R. Murray, 146, Main Street, Barrhead.

April 1, 1906.—Coatbridge Co.-Op. C.C. Hon. Secretary, James Robb, 6, Windsor Terrace, Blanhill, Coatbridge.

April 18 to 20.—Southend-on-Sea exhibition. Hon. Sec., J. Archer, 24, Ashburnham Road.

April 20-21, 1906.—Watford Photographic Society. Hon. Secretary, C. J. Trevarthen, Ashcroft, Bushey Hall Road, Watford.

May, 1906.—Warrington Photographic Society. Hon. Secretary, A. C. Smithson, 13, Chester Road, Warrington.

FORTHCOMING COMPETITION.

December 30.—Royal Photographic Society "Affiliation" Lecture Competition: (a) Illustrated lecture descriptive of a tour (b) Illustrated technical lecture. Particulars from the Secretary R.P.S., 66, Russell Square, London, W.C.

Patent News.

Process patents—applications and specifications—are treated in Photo-Mechanical Notes."

The following applications for Patents were made between November 27 and December 2:—

PRINTING APPARATUS.—No. 24,544. Improvements in photographic printing apparatus. George Smith Bratby, 6, Lord Street, Liverpool.

COLOUR PHOTOGRAPHY.—No. 24,586. A process of printing photographs in colours. John Wagner, 3, Edinburgh Mansions, Howick Place, Victoria Street, London.

CAMERAS.—No. 24,803. Improvements in and relating to photographic cameras. La "Vega" Soc. Anon. de Photographie et d'Optique. 52, Chancery Lane, London.

CAMERAS.—No. 24,813. Improvements in or relating to photographic cameras. Walter Tully, 76, Benedict Street, Glastonbury, Somersetshire.

RETOUCHING.—No. 24,816. An improved appliance for the retouching of photographic negatives. Thomas Stephen Bruce and James William D'Anter, 4, Villars-on-Heath, Hampstead, London.

COLOURED LIGHTING.—No. 24,875. Process for the simplified correction of the chemical effect of the spectrum in reference to photographic purposes by means of coloured illumination of the object to be photographed. Gottlieb Krebs, 27, Chancery Lane, London.

PRINTING APPARATUS.—No. 24,964. Improvements in printing apparatus for photographic purposes. Edmund Schneider, 6, Lord Street, Liverpool.

DISHES.—No. 24,990. Improvements in dishes or trays for photographic purposes. Alfred John Rixom, 108, Park Road, Loughborough, Leicestershire.

COPYING MACHINE.—No. 25,040. An improved method of and machine for copying photographs. Edward Russell Clarke, 18, Southampton Buildings, Chancery Lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

MOUNTING AND FRAMING PHOTOGRAPHS.—No. 27,144. 1904. . . The claim is for an improved method of mounting and framing photographic or other prints or pictures, in the form of a "plaque." The mount is of special construction, being square, circular, or oval in form, and having a concave surface on which the print may be mounted or supported. The mount, with the photograph mounted thereon, is placed in a frame provided with glass, the surface of which is also concave, so that when the mount and glass are in juxtaposition and having the concave surface towards the outside, the framed picture will thus be in the form of a "plaque." The preparation of the concave glass consists in it being rendered opalescent or translucent, preferably on the concave surface and over such an extent of surface as may be required. Under certain conditions this opalescent or translucent portion may be made to represent the marginal portion of a mount, in which case the concave mount may be greatly simplified, or it may at times be dispensed with. Will Watson, 92, North Park Street, Glasgow.

MAGAZINE CAMERAS.—No. 3,583. 1905. The claim is for a daylight-loading plate or film box, containing a series of plate or film holders or sheaths which are hinged together or arranged book-wise; the box having externally-operated mechanical means for opening and closing, for controlling the feed of the plates in succession into the focal plane, for positioning them for exposure, for releasing each plate after exposure so that it may fall or be transferred into a receptacle formed by a part of the open box, and for re-enclosing the exposed plates within the box on the latter being closed. Also for the application of the same principle to photographic cameras, and in the employment of externally-operated means for opening and closing the changing box when in position inside the camera. George Wilkes, The Yews, Stechford, near Birmingham, and Arthur John Leeson, of 59, Temple Row, Birmingham.

News and Notes.

WOMEN in the Photographic Trade.—There is a delightful frankness about a letter in the "Daily Mirror" of last week. A feminine worker, it appears, travels for a wholesale firm of photographic and optical dealers, and she takes more orders than any of the men travellers in her firm. She is in favour of dressing in men's clothes and of receiving men's wages. Advanced ideas to emanate from the Kennington Park Road, whence writes this champion of her sex!

PROPOSALS are on foot to establish a photographic society at Ryde, Isle of Wight.

THE Photographer in Daily Life.—Last week, at Willoughby, near Rugby, a photographer named James Seckington, made a gallant attempt to rescue an old man from a burning building.—In Birmingham last week William Barrett, photographer, of Ridley Street, was cut about the leg during an altercation with several other men. It was alleged that a woman was the cause of the incident.

NATIONAL Photographic Record Association.—A Council meeting was held on Friday, 8th inst., Sir Benjamin Stone, M.P., president, in the chair. One hundred and ninety-eight prints have been received since the last meeting. The president had contributed a series from Uxbridge, including the Treaty House, a set from Hereford, including the chained library in All Saints' Church, and others from Compton Wyngates, Burford Priory, Chipping Campden, etc. An

interesting series of life in the East End of London was sent by H. T. Malby, and the association had received from Mrs. C. W. Ward a series of fonts from Winchester, Kent, Devon, Derby, etc., from Mr. G. Bingley copies of the old charters (thirteenth century) of Allerton and Kirksall Abbeys, Mount Grace Priory, Yorkshire; Thornton Abbey, Lincolnshire; Burnsall Church, Yorkshire, and a series from Monasterboice, Ireland; from Mr. F. Scamell, a set of the motor trials for the Gordon Bennett race in the Isle of Man, and from the Hon. Secretary, Mr. Geo. Scamell a series of churches at Writtle, Margaretting, Ingatestone, Fyfield, Newport, L'Baddow, etc., in Essex; and from Sandwich, Deal, etc., in Kent. All these prints were accepted and ordered to be forwarded to the British Museum. The total number of prints now received for the collection is 3,683. The Hon. Secretary, Mr. Geo. Scamell, will be glad to receive any suitable prints which can be sent to his address, 21, Avenue Road, Highgate, London.

THE microphotoscope, according to the "Engineer," is the invention of a Berlin chemist. Though no larger than a cigar case, it permits of consulting the map of a whole district by night as well as by day. The map is photographed in miniature on a plate of ground glass, which is illuminated by a small incandescent lamp supplied, when required, with current from a battery, while a lens can be adjusted to the observer's sight.

DEATH of Mrs. A. L. Henderson.—We regret to announce the death, on December 8, of the wife of Mr. A. L. Henderson. Mrs. Henderson had been in failing health for some time, and her death takes place within a month or two of the celebration of the fiftieth anniversary of her marriage. We are sure that Mr. Henderson will have the sympathy of many friends in his bereavement.

STOLEN GOODS.—We are asked to draw the attention of any firms in the photographic trade, or any private persons who have lost goods, to the arrest on Thursday last week of two men who appear to have been carrying on systematic frauds for at least two years past. The police have now in their possession a number of articles which they are not able to identify, and any person who can assist them to do so, and so incidentally perhaps recover property stolen from themselves, should inspect the goods at the City Police Station, The Minories, E.C. The goods consist of some six cameras, several dark slides, lenses, printing frames, an enlarger, a number of chemicals, and a banjo marked in pencil "Southampton," but having no other decipherable mark.

THE current number of "Harper's" opens up still another field for the outdoor naturalist-photographer. The trails of animals in the snow have been studied by Ernest Harold Baynes, whose photographic records of his observations are of a kind to make one wish he had said something of his methods. Mr. Baynes shows the refinements of field-craft, which are to be mastered by persistent practice. A few blotches on the snow, which mean nothing to the uneducated eye, are seen by the Sherlock Holmes of the fields to have a story in them, usually the tragic one of the animal pursued by his natural destroyer.

BANKRUPT Aberdeen Photographer.—James Ewing, photographer, Crown Street, Aberdeen, was examined last week in bankruptcy before Sheriff Reid. Bankrupt; who had conducted a very successful business for about 15 years, accounted for his financial difficulties partly through competition and dull trade. He had never spent money extravagantly, nor had he used money on the Stock Exchange. He had never, in fact, speculated a penny. He had lost a few hundred pounds, however, in connection with the Albert Hall Company, of which he was a director. He had also other losses, and these had crippled him so that he was unable to meet his liabilities, which he had estimated at £1,870. When the estate was divided the claims amounted to £1,929. The statutory oath was administered.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Dec.	Name of Society.	Subject.
15.	Aberdeen Amat. Photo. Assn.	Photography Prize Slides.
15.	Bromley Camera Club	Lantern Lecture. Messrs. G. W. Smith and W. L. Crossley.
15.	Colne Camera Club	"Candle-light Photography." Mr. J. Paterson.
16.	Aberdeen Photo Art Club	"Foundations of Modern Architecture." Mr. H. David.
16.	Motherwell Y.M.I. Cam. Club	"Velox and New Application." Mr. W. Sadler.
16.	Stafford Photographic Society	Pictures with the Goerz Lens.
16.	Dewsbury Photo. Society	"Naples." Mr. Thos. E. Green.
16.	Halifax Camera Club	"How to Make Lantern Slides." Mr. F. Nicholson.
16.	Scarborough and Dis. Ph. Soc.	Members' Night. Lantern Slides and Prints. Mounts and Framing, &c.
16.	Southampton Camera Club	"St. David's Cathedral." Mr. A. E. Henley.
16.	Oxford Camera Club	Exhibition of Members' Slides.
16.	Cripplegate Photo. Society	"Development and Toning of Bromide Papers." Mr. J. B. Bensley.
16.	Hastings and St. Leonards P.S.	Ten Minutes' Lectures. Members.
16.	Bowes Park and Dis. Ph. Soc.	"The Society's Outings." Mr. F. C. Hornsey.
16.	Wandsworth Camera Club	Jumble Sale.
16.	Heaton & Dis. Camera Club	"How to Make Enlarged Negatives on Bromide Paper." Demonstrated. Mr. J. T. Carnaby.
16.	South London Photo. Society	Excursion Lantern Slides, Novices Print, and "Peace" Competitions.
16.	Manchester Amat. Photo. Soc.	"Toned Lantern Slides." Mr. J. D. Berrick.
16.	Darlington Camera Club	Exhibition of Members' Lantern Slides.
16.	Nelson Photographic Society	Y.P.U. Members' Print Portfolio.
16.	St. Helens Camera Club	"Photographic Notions." Mr. W. Inman.
16.	Gateshead Camera Club	"Cloud and Cloud Printing." Mr. Greaves.
16.	Glasgow Southern Photo. Assn.	"Our Camping Experiences." Illustrated.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, December 12. The Rev. Henry W. Dick read a paper on "Art in Photography," in which he put forth the view that art was essentially the expression of feeling, and a work of art implied the possession of feeling on the part of the artist. Art might then take the shape of music, sculpture, painting, or photography, and the lecturer would not have photographers take too modest or limited a view of the power of photography as a means of expression. A discussion followed, in which Messrs. J. C. S. Mummery, J. C. Warburg, P. Bale Rider, and others took part.

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

The monthly meeting of the Committee was held at 51, Baker Street, W., on Friday, December 8. Present:—Messrs. F. A. Bridge, Alfred Ellis, E. C. Elliott, S. H. Fry, H. E. Hull, Wm. Grove, A. Mackie, E. Scamell, Lang Sims, and R. Fellows Willson. In the unavoidable absence of the president Mr. Alfred Ellis, past president, took the chair.

The publication of the second number of the "P. P. A. Circular" was reported.

The Secretary reported that, in accordance with the decision of the Committee, a circular letter had been addressed to all those who had sent for the prospectus of the Certificate Scheme and had not followed the matter up by applying for certificates, asking the reason they had not done so, and for suggestions for modifying the system so as to meet their requirements. The replies already received were read, and the objections principally raised were summarised, as follows:—Fees, too high; the special provision for outdoor operators; the term second grade as at present applied to a thoroughly competent operator in a good middle-class business. A lengthy discussion took place, and it was generally agreed that the objections raised were all well worthy of consideration. A suggestion was made by Mr. Fry that the scheme did not sufficiently provide for that class of assistants who, perhaps, constituted numerically the largest class, which might be described as general assistants, and were expected to be able to carry out successfully any part of the work of a photographer's business they might be called upon to do at the moment. The chairman thought that it would be wise to base their inquiries, when a certificate was applied for, upon a statement by the applicant of what he considered he could do, to be verified or otherwise by inquiry of the employers referred to. Mr. Mackie thought that in their anxiety to be perfectly candid in publishing the questions to be put to employees they had misled some who would have become candidates by suggesting that proficiency was required in all the branches of photography that were referred to. A sub-committee was appointed to consider the whole question and report.

Two cases of infringement of members' copyright by newspapers were reported. In one the Secretary had arranged a satisfactory settlement, and his action in the other was approved.

The receipt of the draft "Copyright Act" of the Artistic Copyright Society was reported, and a subcommittee was appointed to consider it with a view to the members representing the association on the society presenting the association's case at the meeting of the society on the 14th inst.

The next meeting of the Committee was arranged for the third instead of the second Friday in January.

OXFORD CAMERA CLUB.—Meeting held Monday, December 11, Miss Venables in the chair. A lecture was given by Mr. George E. Brown (Editor of the *BRITISH JOURNAL OF PHOTOGRAPHY*) on "The Property Value of Photographs," in the course of which the present state of the law relating to copyright in photographs was explained. A somewhat lengthy discussion followed, in which a number of ladies and gentlemen took part.

PLYMOUTH PHOTOGRAPHIC SOCIETY.—"Landscape Photography," one of the affiliation lectures, by Mr. G. T. Harris, F.R.P.S., engaged the attention of the above society on Dec. 8, the last meeting of the session. Mr. F. Johnson presided, and Fleet Engineer R. A. Shapcott, R.N., read the paper. The point which brought out most discussion was the contention of the writer for great sharpness of definition on the focussing screen, giving instructions for the use of microscopic slide glass for producing clear glass on the screen for the securing of it. All the slides used in illustrating the subject were characterised by keen sharpness and much brilliance, everything in the slide being equally crisp and clean cut. The members were not agreed that this was desirable for artistic effect, there being no breadth of treatment in evidence. The use of colour screens as light filters were illustrated, and the value of some for over-correction—to produce a certain result—were considered by the writer. In an example or two thrown on the screen the members were not in agreement with the writer of the paper, because effects were produced which might have been a true rendering from a scientific point, but were not of a character to enhance the artistic quality of the picture. The advice of the writer to take an assortment of several speeds for a projected day's work was not approved, because it was pointed out that if a subject demanded a very fast plate it was of no, or very little, use to try a slow plate upon it, but a good fast plate would be useful in any connection. It was said that Sir William Abney had pointed out there was a more correct orthochromatic rendering with a rapid ordinary plate than with a slow one, which some agreed with. On the whole, the paper was considered as somewhat out of date or not up to the present ideas on landscape photography.

Commercial & Legal Intelligence

UNAUTHORISED REPRODUCTION.—In the High Court, on December 10, Mr. Mark Romer moved *ex parte* before Mr. Justice Buckley in the case of *Lee v. Lafayette* for an injunction restraining the defendants, photographers, of New Bond Street, from publishing or authorising to be published photographs of Mrs. Lee taken in the ordinary way and on the ordinary terms. Mrs. Lee, said counsel, was taken in two positions, and a reproduction of one of the photographs appeared in an illustrated paper. Mr. Lee went to the defendants and saw the manager of the publication department, who expressed regret and gave an assurance that there should be no repetition of what was complained of. Subsequently the other photograph was reproduced. In granting an *ex parte* order over next week the judge said the motion was made as a protest against the offensive vulgarity of the present day in reproducing people's photographs, even on postcards, without their permission.

OLD BILL-HEADS.—Mr. C. H. Perry, trading as Reed and Co., 28, Paternoster Square, had recovered a judgment for £5 (less 10s. allowed since against Mr. Frank E. S. Perry, trading as the Direct Photo Engraving Company, 38, Farringdon Street, for goods supplied. When execution was levied, the firm of Perry and Wilson claimed the goods. Mr. Frank Perry, the defendant, said that he was sued personally when the firm ought to have been proceeded against. Mr. Hickman, solicitor for the plaintiffs, said that as recently as July the plaintiffs received a bill-head from "The Direct Photo Engraving Company, Frank E. S. Perry proprietor." Wilson was a sleeping partner. Mr. Frank Perry said that the bill-heads referred to were used by mistake. The Judge said he would amend the judgment, and make it against both Wilson and Perry, and then their claim to the goods would be barred. Perry and Wilson must pay the costs of the proceedings.

Correspondence.

* * We do not undertake responsibility for the opinions expressed by our correspondents.

THE KEEPING PROPERTIES OF DRY PLATES.

To the Editors.

Gentlemen,—I would esteem it a favour if you would let me know how long a dry plate retains its sensitiveness. My reason for enquiry is that I have exposed an Ilford ordinary plate, which has been in my possession since 1887, a few days ago for curiosity, and, to my astonishment, it came up as vigorous as a fresh plate. I enclose you a print (rough) from the negative for inspection. Thanking you in anticipation, I remain, yours truly, R. GIBSON.

114, George Street, Limerick, December 12, 1905.

[We insert our correspondent's enquiry in this place, as his experience seems to be almost a record among instances of gelatine plates retaining their good properties for a long period. The print sent to us is remarkably clear—evidently from an excellent negative.—Eds. B.J.P.]

COPYRIGHT IN CINEMATOGRAPH FILMS.

To the Editors.

Gentlemen,—Your paragraph in "Ex Cathedra" last week raises a point which no doubt will some day prove a bit of a puzzler for the courts of law, but, as a maker of film, I would draw attention to a matter which calls for redress with much greater urgency. As you know, and as probably a large section of the public knows, producers of cinematograph films incur great expense in preparing subjects of the story and incident class. Models have to be found, costumes made, scenery painted, and an immense amount of thought expended before everything is in readiness for the taking of the negative. Then as soon as the film is on the market it is not at all unusual to find another maker copying the story, incident for incident, and thus robbing the originator of the just fruits of his invention. A really taking film is not an easy thing to produce. Out of a dozen which may be made, only one most likely will be acceptable for exhibition purposes. The film pirate—if I may use the term—steals the cream of one's labours, and there seems no remedy for or preventative of his sharp practices. I should like to hear the views of yourself or of others on this point, which constitutes an open sore at present in the cinematograph trade. Meanwhile I am, Gentlemen, yours very faithfully,

FILM-MAKER.

December 13, 1905.

[We will refer to this matter next week.—Eds. B.J.P.]

THE FREE PORTRAIT SWINDLE IN WEST LONDON.

To the Editors.

Gentlemen,—You do a great service to photographers by your exposures of the frauds which are perpetrated on the public by unscrupulous persons whose presence in the photographic field is a danger as well as a discredit. I read your remarks of late on the various forms of free portrait swindle, and may therefore notify you of the practices of a firm which have just commenced operations in Shepherd's Bush. It is the usual story. The canvasser calls with the threadbare yet plausible story of his firm inviting twelve only of the leading residents to accept an enlargement of their portrait. He takes away the photograph, and the next thing is an application from the firm for 12s. 9d. for a frame. A visit to the office brings the victim into touch with another member of the gang, who repudiates the canvasser's offer of a free portrait. And so the game is played, unless the men are told that unless the photograph is returned at once the matter will be referred to the police.

A CENTRAL LONDONER.

December 12, 1905.

Answers to Correspondents.

- * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.
- * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- J. Fenner, Partridge Green, Sussex. Photograph of Monument erected to Maria Fitzherbert in Church of St. John the Baptist, Brighton.
- Isabella Fielding, 10, Kellins Street, Tooting, London, S.W. Photograph entitled, "The Disabled Bread Winner."
- A. D. Coon, 72, Park Street, Dundalk, County Louth, Ireland. Photograph of the Dundalk Orchestral Society.

PHOTOGRAPHS ON LINEN.—(1) Will you please inform me the best method of producing permanent prints on silk or linen that will stand washing frequently, such as a handkerchief with small photograph in corner? (2) Can you give me formula for making a waxing solution for preparing ferrotype plates to enable squeezed prints to detach easily?—CARBON.

(1) The following is a simple method:—Wash the linen well and dry. Then immerse the handkerchief in a warm solution of gelatine* containing three grains of gelatine and ten grains of chloride of ammonium to the ounce of water. Wring out and allow to dry. Iron with a hot iron to make smooth. Then, at the part where the photograph is to be, sensitise with an eighty grain solution of nitrate of silver, applied with a brush; dry, print, tone, and fix as a paper picture. On page 844 of the Almanac is a method of producing photographs on fabrics by an iron process. (2) Beeswax, five grains; benzole, one ounce.

J. D. EDWARD.—See reply to "Carbon."

BLISTERED PRINTS.—I have been much troubled lately with blisters on bromide paper and postcards, both ordinary and gaslight. I develop with hydroquinone, and the blisters do not come up until the prints are being washed after fixing. I use ordinary hypo, same strength as for plates, for fixing. Can you give me any hint as to cause of trouble, and suggest probable remedy? I enclose a badly blistered postcard for inspection.—H. M. CAMPBELL.

Although the blisters do not come up until the prints are in the washing water, we judge by their appearance that the blisters have their origin in the fixing bath. We should advise you to use hypo weaker, say two ounces to the pint of water, and leave the prints longer in it to compensate for the weakness. Also take care that the solution is no colder than the washing water.

LABY OPERATOR.—1. As the studio will be situated, as regards the surroundings, we would suggest that five feet, or five feet six at either end, side and top, be made opaque. The rest may be glazed. You will then have the convenience of being able to use both ends of the studio. 2. Better, with this aspect, have glass on both sides. 3. Have a good slope to the roof.

If you get Bolas's work, "The Photographic Studio and its Construction," it will give you a deal of information. Its price is two shillings.

ACID BATH.—Can you give me a really good formula for an acid hypo bath that will take all the yellow colour out of a pyrosoda negative? One that is easily made up, and not too many chemicals required. Into an ordinary plain hypo bath I put an ounce of pulv. alum and about 5 drops acid sulphuric. This successfully took all the colour out, but the solution went at once very cloudy and milky, and the negatives were rather dirty; that is, there were dirty marks on the film just as there often is with ordinary hypo, only that the film was so much hardened by the alum that the marks could not be rubbed off with cotton wool. Can you tell me if this bath is bad for the plates, and that if proper washing is given, will they fade or stain in time when dry?—S.E.

Certainly the bath is wrong. You will find the standard formulae on page 954 of the "Almanac." Perhaps the simplest formula is—Hypo, 4 ozs.; potass metabisulphite, $\frac{1}{2}$ ozs.; water, 20 ozs.

BROMIDE.—"Art of Retouching," by Robert Johnson, published by Marion and Co., price 2s.

J. F. SLACK.—See reply to "Bromide." The book there named is the best on working up photographs in oils, etc.

MOUNTING GLAZED PRINTS.—Will you please give a quick and efficient method of mounting P.O.P. prints that have been squeezed on ferrotype plates that only want to be in contact with the mount at the edges?—MOUNTANT.

Apply a thin line of seccotine to the extreme edges of the print by means of a stiff hoghair brush and a piece of flat tin used as a straight edge. The position of the print should be first marked on the mount.

COPPER TONING.—Would you kindly give me Mr. Ferguson's formula for a copper toning for lantern transparencies. The above formula is intended to give red tones, but if you know of any other compound giving a blue tone, I would be indebted to you.—WILLIAM LYALL.

The two following, from the "Almanac" (page 979) should answer your purpose:—

A.—Copper sulphate	60 grs.
Potassium citrate (neutral)	240 grs.
Water	20 ozs.
B.—Potassium ferricyanide.....	50 grs.
Potassium citrate (neutral)	240 grs.
Water	20 ozs.

Use equal parts of each. Warm black to red chalk tones are obtained.

Blue tones—10 per cent. solution ferric ammonium citrate, 2 ozs.; 10 per cent. solution potassium ferricyanide, 2 ozs.; 10 per cent. solution acetic acid, 20 ozs. The well washed prints are immersed in this bath until the desired tone is given. Then wash well until high lights are clear. This bath intensifies the image.

A. L. COON.—The lighting is too flat, by reason of the flash-lamp being almost straight in front of the middle of the group. The light was also much too low for a group this size. It should have been at least 20 feet up, and proportionately brighter. The best results, for a group, are obtained by using two lights, one very strong and high up, and the subsidiary light lower. There is no blow-through lamp in which flash powder can be used. Plain magnesium only should be employed with these lamps.

C. V.—1. A daylight studio, if you can have one, with dark blinds, is what we would suggest. You can then economise artificial light. You will find several artificial lights advertised in our pages. 2. The Sinop process (Penrose and Co., 109, Farringdon Road, London, E.C.).

COPYRIGHT.—I read through your article on "Copyright" in the "Almanac." There is one point you have not touched on, and it is a most interesting one to photographers. Supposing I am paid the full price I demand for photographing a person, a group, or an object, can the person, or one of the group (say a football team), without my permission, and perhaps against my will, hand over one of these photographs to a newspaper for reproduction purposes. Can I demand and make that paper pay me a fee? When taking the photograph there was no stipulation as to reproduction, and I believe the sitter was not aware at the time that the photograph would ever be reproduced. 2. Who can I procure mercury-vapour lamps from?—DEFIED.

1. You will find that the case you instance is referred to several times. Certainly you have no copyright in the photograph. You have been paid your price, and the copyright belongs to the person who gives you the order. 2. Penrose and Co., 109, Farringdon Road, E.C.

BROMIDE PAPER.—1. Is there any value in the residue obtained from the burnt ash of bromide paper after it has been developed and fixed? 2. Should you say that a hypo-alum bromide toning bath would suffer in any way from being continually worked in a galvanised iron dish or tank? I wish to know if it would act on the iron in any way prejudicial to the toning of the prints. 3. Could you tell me if there is published, and if so where I could get a treatise dealing with the hypo-alum method of toning bromides. 4. I enclose you a postcard which has become stained. What theory would you put forward as a probable cause of this bleaching or staining? The card was a contact, printed, developed, fixed, and washed in the usual way. It was then glazed, and when dry came off the glass as you now see it.—ARGENTYPE.

1. Very little. Write to one or other of the refiners whose advertisements you will see in our columns. 2. The bath is liable to become acid, and would then dissolve iron. We should prefer not to use an iron tank. Zinc would be free from objection. 3. "Toning Bromides," by C. W. Somerville, or "Toning Bromide Prints," by Blake-Smith, 1s. each. 4. The stain looks as though the print had been forced in development, otherwise we are at a loss to account for it.

GEO. WOOD.—The best book for your purpose is Abney's "Instruction in Photography," or, if you read German, Eder's "Photographie mit Bromsilber Gelatine."

"VECTIS" and others.—In our next.

FLASHLIGHT.—I understand there is a method of firing off flash powder from portable electric arrangement. Can you advise me how this is done, or where such can be obtained? I should like to apply it to my present lamp, and in other ways, outside as well as indoors.—F. E. G.

You will require a storage battery. To this attach two insulated wires of sufficient length to reach the lamp. Between the ends, attach a piece of fine platinum wire so that the current has to pass through it. The length of this wire should be about a quarter of an inch long between the terminals, which are laid in the flash powder. Then when the current is switched on the platinum wire is rendered incandescent and fires the powder.

SILVER RESIDUES.—I have collected a large amount of waste P.O.P., and also the hypo in which hundreds of roll films have been fixed. Would you kindly inform me, through your paper, how I could dispose of this to good advantage, and also how best to reduce it to a metallic state, if necessary?—SILVER.

Burn the paper to a fine ash, and precipitate the silver of the fixing solutions with sulphide of potassium (liver of sulphur). Dry and mix with the ash, and then send to a refiner. If there is a large quantity of each it is advisable to keep them separate. Unless you have a good quantity of the residues to deal with, they are barely worth the trouble of saving. Have you read the article on the subject on p. 703 of our issue of September 8 last?

INK PRINTING PROCESS.—1. I am anxious to make my own printer's ink for above process. Would you kindly oblige by giving me a formula for same? 2. Do you consider the process a permanent one?—D. LAIDLAW MURDOCH.

We think you would do much better to buy the ink than attempt to make it yourself in small quantities. However, here is a formula, which we cull from Cooley's Encyclopædia: Indigo and Russian blue, each 2½ oz.; mineral lamp black, 4 lb.; vegetable black, 3½ lb. Stir gradually into the warm varnish. The varnish is made as follows: 10 to 20 gallons of linseed oil is boiled and then set fire to, and let to burn for half an hour or so, when the flame is put out by putting a cover on the vessel. This is a dangerous operation, and should be conducted out of doors for fear of accidents. Of course, you can reduce the quantities to suit your requirements. 2. Yes, certainly.

H. H. (Glasgow).—The formula is that given in the original paper.

PACKING Prints.—In reference to our paragraph last week, Messrs L. Canesi and Co., makers of postal wrappers, write us:—"We agree with you in what you explained, with the exception that the use of sealing-wax for parcelling photographs is out of the question, and the use of corrugated cardboard, which appears safe, is not so suitable as a solid cover. A properly made postal wrapper does not require all those unnecessary materials, which only increase the weight, price, and labour, and they will not enhance the contents on account of having a clumsy and patchy appearance." Messrs. Canesi send us a number of postal wrappers of their manufacture which we have found to resist rough usage to a remarkable degree.

A CORRECTION.—On p. 935 of the "Almanac" for 1906 an error occurs in the description of a reflex camera, which should be entitled the "Royal," and credited to Messrs. A. E. Staley and Co. 19, Thavies Inn, London, E.C.

*** NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

Sensitising Carbon Tissue. As will be seen from our Patent News column, a patent has been taken out in this country by a German firm for improvements in sensitising carbon tissue. The improvements consist in mixing with the aqueous solution of the bichromate salt a certain proportion of a volatile liquid (acetone being specially mentioned), which evaporates quickly, so that the tissue dries rapidly, and thus the insolubility, which a very prolonged drying brings about, is avoided. The solution is to be swabbed over the tissue with a pledget of cotton wool, a method which was by no means unusual in the early days of the process. It was common to sensitise the tissue on its surface only, by floating it on the bichromate solution, as albumen paper was sensitised on the silver bath: or it was sometimes sensitised by applying the solution with a flat camel-hair brush. It was claimed, at the time, for this method of sensitising the surface only that, for certain purposes, it was preferable to entirely immersing the tissue in the solution. Although this method was said to possess some advantages, it was never largely followed, possibly by reason that it was more trouble than the total immersion of the tissue, and that there was the chance of obtaining an unequal sensitising of the pigmented coating. With the second part of the invention one may ask where is the novelty in the addition of a volatile liquid to the sensitising solution? It has long been the custom in England—when it is desired to dry the tissue quickly—to replace part of the water in the solution of bichromate with a volatile liquid—alcohol (methylated spirit) being the one employed. Another method of quick drying of the sensitised tissue is to immerse it in methylated spirit to abstract much of the water; it will then dry very rapidly, and a gentle heat may even be employed to accelerate the drying without fear of the pigmented gelatine coating running off the paper.

Many, possibly, may not be aware of the large extent to which spirit may be made to take the place of water in compounding the bichromate solution if a considerable proportion of liquid ammonia be added to it. The ammonia, however, does no harm, as it all evaporates as the tissue dries, and leaves only the bichromate of potash behind. As the carbon process has hitherto not been so generally worked in Germany as it has been in this country, it is possible that the German patentees are not familiar with what is being and what has been done here.

Photo Buttons.

Everyone will remember the craze of about the time of the Boer War for photo-buttons, and the ready sale they had, especially those with portraits of the different generals then in the field. They were not, however, utilised as buttons for garments, but were provided with pins and used rather as brooches. These have now given way to miniatures, worn as pendants or as lockets by ladies who see fit to adorn themselves with cheap ornaments. We now learn, on the authority of an evening paper, that bonâ-fide picture-buttons are coming into vogue, and we have ourselves seen examples of the craze in the City shop windows. According to the "Evening News": "The latest foible—and tailors say it is very keen amongst the dressed-up-to-date—is to have portraits of women by Gainsborough and other famous artists reproduced in miniature on the buttons of fancy vests." If on vest buttons, one may ask, why not on the buttons of other garments—say coats, sleeve links, and such like things? Again, why should the pictures be confined to reproductions of paintings by portrait painters? Why should they not be portraits from life of present and of departed friends? Furthermore, why should the pictures be of the cheapest kind? they might be by the ceramic process fired into the enamel and thus be lasting. If this style of button becomes the fashion, as the contemporary from which we quote intimates is already the case, photographers may possibly find it to their advantage to make a speciality of miniature portraits to be used as real buttons for garments. But we would not recommend any photographer to take an exuberant view of the possibilities.

Condensed Moisture.

The formation of dew or condensed moisture on cold objects is of considerable inconvenience in many ways to photographers. Negatives being printed from out of doors are so cold when brought into the room again that both back and film are almost immediately covered with a thin film of moisture, which is a powerful factor in the production of silver stains if the negatives are unvarnished, and are being printed in albumen or P.O.P. The moisture itself detrimentally affects platinotype prints, causing a muddiness of the whites. Again, in cold weather, moisture is very likely

to condense on the inside of the glass roof of the studio, and to accumulate and trickle down the sash bars. With rather flat or low pitched roofs it will frequently drop to the floor, and unless the weather happens to be dry, may lead to the suspicion that the roof is leaky. Where the roof is well pitched it is easy to place a small zinc gutter at the bottom of the glazing to catch the condensation. In outdoor photography particular care must be taken to avoid condensation of moisture on the lens. It is not particularly liable to occur so long as the lens is kept in the cold atmosphere; but if the hand is placed against the lens a slight steaming on the cold thick glass may be noticed. We have known the cap, after being in the pocket or held in the hand, give off enough moisture to produce noticeable condensation on the lens. The principal danger, however, lies in carrying apparatus some distance in a cold atmosphere, and then taking it into a warm room for interior work or home portraiture. The safest plan is to place all the lenses from the bag in a warm place and leave them long enough to thoroughly warm through. With the modern cemented type of anastigmat the greater thickness of each element as compared with the R.R. type of lens necessitates a longer time in thoroughly warming. On no account should a lens be placed in a hot place, and the rule that there is danger if the hand cannot be comfortably held beside the lens is a good one to follow.

Bromide Prints from Varying Negatives.

In working bromide papers from negatives of varying quality, much better results will be obtained by changing the paper and the developer than by employing such methods as Mr. Sterry's bichromate bath for softening contrast. This device is admirable for exceptional cases, but is not sufficiently practical for the rush of commercial orders. The method of over-exposing and stopping development before it has reached the limit is sometimes recommended, but this, again, is open to the objection that the darkness of the print depends on the exercise of judgment in removing it from the developer. It is practically impossible to get a dozen prints even in depth if this course is adopted. The time of exposure to a uniform light can be repeated exactly, and, with complete development, the results must be alike in depth. Practical methods of altering the contrast of the print are the variation of paper, developer, and distance from printing light. A slow paper gives increased contrast, while a rapid paper breaks down contrast. Amidol tends to give greater contrast than rodinal. A strong negative printed near the light gives a softer result than if printed further away. In certain extreme cases it may be necessary to print on rough paper which appears to soften contrast, the roughnesses of the paper catching light and so breaking up heavy shadows. If rather too rough the prints may be rolled well. Prints which are strong in contrast may often be toned—assuming the client will approve the sepia colour—by the bleaching and sodium sulphide method, and when in the brown shade the contrast is not likely to appear so strong as if in black.

Cinematograph Subjects and their Piracy.

The injury suffered by the producers of cinematograph films who have gone to very considerable cost and trouble in their production and in their inception, a subject we alluded to in "Ex Cathedra" a fortnight ago, is fully confirmed in a letter from a film maker, published in our last issue. Our correspondent points out that not only are the films themselves pirated, but in many instances, after a film has

caught on the market, the story is copied incident for incident, other models and scenery being used, and thus the originator of the picture is robbed of the fruits of his invention. Assuming that the present Copyright Law, by a single registration of a film, covered the hundreds of pictures of which it is composed, it would not prevent anyone from producing similar films by employing other models and other scenery, for, in the words of the Act—"Nothing herein contained shall prejudice the right of any person to copy or use any work in which there shall be no copyright, or to represent any scene or object, notwithstanding that there shall be copyright in some representation of such scene or object." Where is the remedy for cinematograph film piracy? Magistrates have often remarked in the police courts that if there were no receivers there would be fewer thieves. If there were no purchasers of pirated films there would be no piracies. But we fear, as with pirated music, there will always be purchasers for what is to be had perhaps at a lower price; hence a remedy is hardly to be expected in that direction. It has been suggested that the reputable film producers should combine, as the music publishers have done, and take concerted action in the matter. The question then might be submitted to counsel versed in Copyright Law, and perhaps an action raised in the Law Courts as to whether the registration of a film in its entirety covered the copyright in all the pictures in it. If this were decided in favour of the authors of the works it would put an end to the piracy of the films themselves. If not, the authors would be in no worse position than they are at the present time, and the costs would not be great when contributed to by all the leading film producers, especially if counsel's opinion were against action being taken.

* * *

A Filmic Literary Work.

The point raised by our correspondent last week is, however, one of more pressing importance, as it undermines the foundations of the cinematograph film business. Yet we see no remedy for the evil in the Artistic Copyright Act, and the only suggestion we have heard put forward is such an extremely fanciful one that we think its applicability to the problem may almost be scouted offhand. It is the proposition that a film of the "incident" kind is practically a story—told not in words, but in pictures. If it's a story, why not grant it the protection accorded to literary works? The spectacle of the authorities at Stationers' Hall filing 500ft. of film as the "manuscript" of a literary work, alongside the hand or type scripts of Sir Conan Doyle, is one suggesting the extravagance of Gilbertian opera; and yet an evolutionist standing by would see in the action only a curious reversion to the oldest forms of recorded characters, the twentieth-century cinematographer bridging the gulfs of history which separate him from the ancient cave-dwellers and their picture writings. But we fear it would require all the casuistries of eminent counsel to convince a justice that such a course was right in law; and for the present we see no means of palliating the evil.

* * *

A Possible Remedy.

A more hopeful direction in which to turn for remedy is in copyright law as it affects dramatic works. We must confess to a very short acquaintance with this peculiarly intricate branch of Copyright, but we believe that a certain measure of protection is obtainable for a play in dumb-show, to which the exhibition of a cinematograph film of the "story" order very closely approximates. Protection of this kind would presumably be no preventative of production or sale; but if it could be enforced it would restrain exhibition which is good enough for any film

maker. However, any suggestions must be speculative, as no case has ever come into court to our knowledge, and it is obvious that the trade lacks a precedent on which to establish its rights. The Professional Photographers' Association, we learn, are meeting to consider the proposed Copyright Bill, to which we refer on another page, and we suggest that they will not be exceeding their duties if they take cognisance of the uncertainty also of the proposed Bill as regards cinematographic subjects.

Right to use a Customer's Negative.

In the issue for last week it was mentioned that a motion ex parte had been made for an injunction to restrain Messrs. Lafayette, of Bond Street, from reproducing the portrait of one of their customers, taken in the ordinary course of business. The case came on for hearing in the Chancery Court, before Mr. Justice Buckley, on Friday last. It appears that a lady, Mrs. Lee, sat for her portrait in two positions. Some time afterwards, one of the portraits was published in "The King." The husband of the lady complained to the defendants, who expressed regret, and promised that there should be no repetition of the occurrence. Subsequently, however, reproductions of the other portrait appeared in "Black and White" and in "Madame," and hence the action. The counsel for the defendants expressed regret for the mistake which had resulted in the portrait appearing in the last-named papers. He said that they thought that when they saw the plaintiff's portrait in the "King" that permission had been given to them, and therefore sent copies to the other papers. When a protest was made, he said the defendants did their best to recall; at the same time, he added, that 99 per cent. of sitters usually gave permission for publication. Counsel further said the defendants were now willing to pay the costs of the motion for an injunction, and to submit to an injunction. The counsel for the plaintiff asked for an injunction, for delivery up of the negatives, and costs. On this the defendants' counsel said that the negatives were their property. To this the other side replied that the defendants owned only the glass; what was on it belonged to the plaintiff—a statement which evoked some laughter in court. Finally, the defendants undertook to deliver up the negatives. In the course of the case Mr. Justice Buckley made some strong remarks on the publication of portraits. In delivering judgment, he said he was sorry to hear the arguments put forward, that this age was so vulgar that they were entitled to assume that this lady was a party to this vulgarity, and willing to have her photograph published. The defendants were not entitled to do anything of the sort, and therefore an order for an injunction was made, and the defendants ordered to pay the costs.

Ownership of Negatives.

The delivery up of the negatives which arose in the above case was resisted by the defendants, on the ground that they were their property. Ultimately, however, probably with the view to making some amends for the annoyance caused to the sitter, they agreed to give them up, so that the Court was not called upon to give a decision on that point. In the case of infringement of copyright, all negatives, plates, blocks, etc., become forfeited, but there has, up to the present, not been any decision with regard to the forfeiture of negatives when they have been misused. Hence the matter rests as it always has done—namely, that the negative is the property of the photographer, but he has no right to use it for any purpose of his own without the consent of the sitter. If he does, he lays himself open to an action at law and to being mulcted in costs, as in the above case.

BUSINESS WASTE.

As the close of the year draws near photographers will be turning their thoughts to the annual balance-sheet. It is good to occasionally know just how one stands, to be able to see definitely whether business is increasing or declining, and to take steps to ensure a continuance in the one case, or to arrest matters in the other. The question of falling business is a very difficult and vital one to many men, and to more there comes the almost as important question of dwindling profits. How many a man has felt that times now are not so good as the times past; probably the balance in their favour is often more imaginary than real, but, however that may be, the present is the time that causes anxiety. There are, of course, many causes for business stringency, but, without going into the whole wide question, we may safely say that one of the commonest is needless waste. We recall as we write a glaring instance of a good business gone wrong. The proprietor was a man who had just the requisite touch of art instinct needful to give individuality to his work, and he was one of those lucky ones who seem to strike success at the first venture. But he would never make or keep an appointment. Customers took their chance whether they could find him in, or whether they would be told that the light was not good. He had a malicious ingenuity in convincing people that they were not satisfied with their proofs, and granting a re-sitting. As this re-sitting was usually arranged by the formula, "Oh, come round some time," there were many that never took place. With such a business there was naturally a careless leakage in every direction, and many people were sorry, but none surprised, when they heard that a principal creditor had foreclosed, and the erstwhile proprietor was offered the position of manager—with a business head to control matters from the desk.

That was a case of waste all round, and the end came speedily, but there are many businesses where there is waste in a greater or lesser degree, and where it prevents the other—the successful—end from arriving in its due time. There is a happy medium between meanness on the one hand and extravagance on the other, and too often men seem unable to hit it. It is very probable that a photographer's wife knows how many loaves should be used in a week, and just how much her total housekeeping should cost; it is even possible that the photographer himself limits the cost of his tobacco. And yet when he gets into the studio he loses his grip of things. His plates come by the gross, and he has never considered that many of them individually cost the price of a loaf, or of half an ounce of his favourite mixture. "It's a good thing to be generous with proofs," and so eight plates are exposed where, with a little care, four would have been ample. Perhaps four of these are retouched where two would have sufficed; and, what with proofs sent out untuned, and the fourteen or fifteen prints made before a dozen are mounted—even if one or two mounts are not spoilt—there is an unnecessary expenditure of from 5 to 10 per cent. of the gross amount received on the transaction. An addition of 10 per cent. to one's income would be sufficient to make the year a satisfactory one, but the addition would be more than this, for the money wasted—10 per cent. of the gross amount—is much more than 10 per cent. pared from the net profits. In the dark-room it is the same; chemicals are wasted and go down the sink as though they were mustard. To leave generalising for a moment, we can recall actual businesses in which the bills for materials are from 15 to 35 per cent. more than they need be.

One very prolific cause of waste is injudicious buying. There are photographers who are over-persuaded, and buy

more than they need. Paper is put on their shelves and remains there until it is spoilt; packets of mounts collect dust, and boxes of plates get pushed behind the boxes of more recent arrival. Particularly is this the case where the control is in the hands of an irresponsible assistant. There are assistants who are so careful of their employers' interests as though they were their own; but there are also many who use materials as though their employers had bottomless purses.

Where there is a drain of this kind, how should it be stopped? Habit is often called second nature—sometimes it is nature at first hand—and it is not a thing easy to be altered. A man who is carelessly generous will not be able to check himself without an effort; the effort will be greater if the fault is simple carelessness without the generosity. A great step in the right direction is to find out exactly how much the leakage is. To do this a simple balance-sheet is necessary, and the first thing to be done is to make a list of everything in the place, including the

boxes of plates which have been opened and partly used, and those packets of paper which have spoilt. It is foolish to make the common mistake of putting them down as assets. It is known that the things are spoilt, and if you write them down as worth what they cost you, you are cheating yourself, and closing the gate to amendment; their original cost should be put down under the head of "loss by preventable waste." Under this head there may be many items, and each one should be hunted up. There may be an accessory discarded for some inadequate reason, or one obtained for no reason at all. If a list could be made of the exact number of plates used, and divided by the number of orders received for each size, the result would prove an eye-opener in many studios.

The question of preventable waste is a burning one in all businesses, and in few more so than in photography. If we have succeeded in directing the attention of any of our readers on what may be a weak spot in their own studio, our purpose is achieved.

DEPTH SIMPLIFIED.

WHILE most photographers devote some little time to the theoretical and mathematical study of depth, very few put the information gained to any practical use. When at work they generally ignore theory, and if they cannot test the effect of a certain stop by observing the image on the ground glass, they simply trust to luck, tempered with a little uncertain knowledge gained by experience.

This is not to be wondered at, considering the complexity of the subject as it is generally expounded, and the erroneous ideas concerning it that are so prevalent. A man who is wedded to the idea that depth is solely governed by focal length and aperture, will never be able to reconcile theory with practice, unless, by chance, he is the fortunate possessor of a lens that works very nearly in accord with theory; and even in that case he is not likely to worry himself with the usually elaborate rules for calculating depth that are to be found in sundry text-books, while experience will soon teach him that tables of depth are altogether inadequate for practical work. A depth-indicating device used in conjunction with the focussing scale will be of very much greater utility than any tables, if properly adjusted to the lens in use, but even this useful device has, in common with the tables, the disadvantage of being adjusted to one particular standard of definition, which standard is in many cases not the one that the user of the lens cares to adopt, or should adopt. It is highly desirable to employ an elastic standard that can be varied according to the subject and the lens used, but unless we have a simple way of calculating depth, and are therefore independent of ready-made tables or other aids, it is difficult to allow for varying standards. The following method of calculation is, perhaps, the simplest that can be devised, and if any reader will take the trouble to master it, he will find that the estimation of depth available with a given lens, stop, and circle of confusion, is, if anything, rather a simpler matter than the calculation and adjustment of conjugate distances when copying on a given scale.

Calculating Depth.

In order to be able to calculate depth without the aid of any tables or other devices, it is not necessary to remember more than one simple dimension (which may be called the "depth constant" of the lens) and the proper manner of utilising that dimension.

Before describing this simple method of estimating depth, we must for a moment consider the tables and what they include. Two are to be found in the "Almanac," one by Sir D. Salomon and the other by Dr. J. J. Higgins. These two tables only differ

by the inclusion of different series of focal lengths and stops.* Both are calculated for a circle of confusion of 1-100 of an inch, and both give what is called the hyperfocal distance for each stop. This hyperfocal distance is the distance of the nearest object in approximate focus when we focus sharply on an infinite distance; and it also is the distance on which we should focus to obtain a maximum amount of depth, extending from half hyperfocal distance right up to infinity. As these facts are not quite clear in the tables themselves, an example may be given. Nineteen feet is given as the distance for a 5 in. lens with F.11. This means that if we focus on infinity all objects beyond 19 ft. are in focus. Also that if we focus on 19 ft., all objects beyond 9½ ft. are in focus; and that the distance from 9½ ft. up to infinity is then the maximum amount of depth attainable with a 5 in. lens working at F.11. The tables do not in any way indicate the depth available when focussing on objects nearer than the hyperfocal distance; neither do they explain that depth with such near objects can be readily calculated with the aid of the hyperfocal distances.

A glance at the tables will show that the hyperfocal distance for any stop is always exactly proportional to the diameter of the aperture, so that if the aperture is, say, halved, the distance is also halved. Therefore, if we know the distance for F.1, we can find it for any stop by the simple process of dividing it by the ratio number of the stop. For example, the hyperfocal distance for a 5 in. lens at F.1 being 208 ft., it is therefore 208/8, or 26 ft., at F.8. For F.11 it is 208/11 ft., or 19 ft.; and so on. Hence, if we simply remember the distance of 208 ft. in connection with the 5 in. lens, we can, by a moment's calculation, arrive at the hyperfocal distance for any stop, and, therefore, at all the information that the table contains.

We can mark the 208 ft. on the lens itself, or, failing that precaution, we can quickly ascertain the distance if it is forgotten, for it is equal to 100 times the square of the focal length of the lens when the circle of confusion is 1-100 of an inch; or, in other words, it is equal to the square of the focal length divided by the diameter of the circle of confusion.

Thus we have only to remember this depth constant (or the way of arriving at it), and the method of using it, to be quite independent of all ready-printed depth tables. We can construct a table in two or three minutes that will contain just the information required, using any circle of confusion we please.

To find the depth available with any stop when focussing on

* The 1906 "Almanac" contains one table only, including all the information given in the other two.

a near distance of a definite number of feet, we need only to remember the following simple rule. Knowing the hyperfocal distance for the stop in use, and the distance of the object in sharp focus, if we divide the product of these two distances by their sum, we arrive at the distance of the nearest object in focus; while if we divide their product by their difference, we get the distance of the farthest object in approximate focus.

As an example, let us consider the following problem:—Suppose we are focussing with a 6 in. lens at F.6 on an object 10 ft. away. What are the respective distances of the nearest and farthest object in focus? Taking 1-100 in. as the circle of confusion.

The depth constant for the lens is equal to $6^2 \div 1/100 = 300$ ft. The hyperfocal distance for F.6 is therefore $300/6$, or 50 ft.

When focussing on 10 ft. the limit of near depth must then be

$\frac{50 \times 10}{50 + 10}$ } or 8 1-3 ft., and the limit of far depth must be $\frac{50 \times 10}{50 - 10}$ } or 12½ ft.

This is a simple example that comes out in round numbers, but, as in practice, we, in any case, round off all numbers, problems such as this are always simple. At no time is there any advantage in being exact to an inch, for the best of lenses will give errors amounting to several inches.

Variations in Depth.

This brings us to the consideration of the varying behaviour of different lenses as regards depth. All methods of calculating depth have one fault in common. The calculations assume conditions that are not, and cannot be, fulfilled by any other than a theoretically perfect lens of an unattainable type. Hence no lens behaves exactly as the formulæ would appear to indicate, while the performance of any particular lens depends on its degree of imperfection, and in some measure on certain details of its construction. These discrepancies cannot well be allowed for, except by the adoption of a special indicating device adjusted to the peculiarities of the lens, and if this is not available little can be done beyond calculating the theoretical depth, and making a certain amount of allowance for probable errors. The first allowance we have to make is for the varying defining power of different lenses. The depth theoretically available may differ most materially from the depth apparently given by the lens, because in the one case we judge by a fixed circle of confusion, and in the other by an elastic standard which varies with the defining power of the lens. Our ideas of "focus" are very critical if the definition anywhere is very acute, but they are lenient if there is no very acute definition to set a high standard. We can, however, bring theory and practice into better accord by the simple expedient of allowing for a very small circle of confusion, say, 1-250 of an inch, with a lens of great defining power, and a larger circle, say, 1-100 of an inch, with a lens of inferior quality that will not give very critical definition in any circumstances. It is also necessary to consider the subject, for if there is no fine detail to show up the defining power of the lens, we may use a larger circle of confusion than would otherwise be admissible. If we are familiar with the lens, and give careful consideration to the subject, it may be quite possible to select a circle of confusion that will give calculated results agreeing more or less closely with the apparent depth obtained with the lens. The smallest circle usually necessary will be about 1-250 of an inch, and the largest advisable about 1-100.

There is yet another allowance we can make. If a lens has a trace of positive spherical aberration, the distances that fix the limits of depth are generally shortened, while with negative aberration they are lengthened. As aberration cannot well be entirely eliminated, such effects nearly always exist, and sometimes the magnitude of the effects is very great. You may focus one lens on a calculated hyperfocal distance, and find that in

accord with theory very distant objects are fairly sharp; you may try the same thing with another lens, and discover that the far objects are so much out of focus as to be unrecognisable. If such a fact is known, you can allow for it by making a deduction from your calculated distance, of a far depth, or by adding to the calculated hyperfocal distance. You must, however, be very familiar with the lens to make such allowances with any degree of accuracy, and the safest course is to use a much smaller circle of confusion in your calculations, and look upon the results as simply representing the margins beyond which it is not safe to expect good focus. The limits of depth thus ascertain are almost certainly wrong in point of fact, and will not allow you to take the utmost advantage of the depth actually available; but they are safe limits, and there is some advantage in that fact.

Useful Facts and Rules concerning Depth.

When we focus on infinity the nearest object in focus is at the hyperfocal distance, and depth extends from that distance up to infinity.

The hyperfocal distance is always equal to the focal length multiplied by the diameter of the aperture, and divided by that of the circle of confusion.

When we focus on the hyperfocal distance the nearest object in focus is at half the hyperfocal distance, and the farthest at infinity, so that depth extends from half the hyperfocal distance up to infinity.

When we focus on half the hyperfocal distance, the nearest object in focus is at one-third the hyperfocal distance, and the farthest at the hyperfocal distance, so that if we represent the hyperfocal distance by H., depth extends from H/3 up to H. when focussing on H/2.

Similarly, if we focus on H/3, depth extends from H/4, up to H/2; or if we focus on H/4 it extends from H/5 up to H/3.

Generally, if we focus on a distance equal to H/n., depth extends from H/(n+1) up to H/(n-1). Therefore a series of distances equal to infinity, H., H/2, H/3, H/4, H/5, etc., is a series of distances of consecutive depths, such as when we focus on any one, then depth is limited by the two adjoining distances. This is the fundamental principle upon which all depth indicating devices, such as the Cornex index, are devised. The rule for finding a series of consecutive depths is also very often of use in ordinary work, as it frequently happens that the distance on which we focus is as nearly as possible some definite fraction of the hyperfocal distance.

If we focus on any distance equal to U, then, if H. is the hyperfocal distance for the stop in use, depth extends from H.U. (H + U.) to H.U. (H - U.).

If a lens gives a small quantity of positive spherical aberration, the distances limiting depth tend to be nearer the lens than the calculations indicate; but if the aberration be negative, the actual distances tend to be greater than the calculated distances. This is, however, not a universal rule.

Depth is unaffected by aperture so long as the caustic surface bounding a spherically aberrated light pencil intersects the plate. In such a case depth does not increase as the aperture is reduced, until the latter is reduced sufficiently to throw the caustic surface behind or in front of the plate, and when that condition is fulfilled the effect of further reducing the aperture is very much less than the ordinary depth formulæ would indicate. As the caustics must intersect the plate in some portions of the image when spherical aberration exists, and as traces of this aberration commonly do exist when very large apertures are in use, the conditions that render depth independent of aperture frequently secure and cause the appearance of great differences between the calculated and observed effects.

Various causes of variations in depth were more fully discussed in THE BRITISH JOURNAL OF PHOTOGRAPHY for August 21 and 28, 1903, and reference may be made to those articles for fuller information.

C. WELBORNE PIPER.

THE WEEK IN HISTORY.

(CONCLUSION.)

The Real Birthday of the Royal Photographic Society.

TO-DAY, December 22, should be a kind of day of celebration in the calendar of 66, Russell-square, for it was an event on this date fifty-three years ago which led to the formation of the society a few months later in 1853. On December 22, 1852, at the Society of Arts, a paper was read by Mr. Roger Fenton on "The Present Position and Future Prospects of the Art of Photography." It inaugurated an exhibition of recent specimens of photography which remained open to public inspection for a week, and was very extensively reviewed and criticised in the Press. I believe that this was the first record of a public photographic exhibition in Great Britain, though I am open to correction on the point, and, indeed, imagine that during the twelve years following the announcement of Talbot and Daguerre's experiments some public exhibition very likely took place, but I have no knowledge or recollection of its occurrence. However, this exhibition at the Society of Arts was comprehensive in its character and a good deal larger than many of the shows which are now held. It included 774 prints, Talbotypes or calotypes, waxed paper and albumenised, glass, and collodion. French, German, and British photographers contributed to it. One item, as recorded in the "Athenæum" report (1853, page 23), may be of historical interest. A book was exhibited by a certain Captain Ibbetson, prepared entirely by photography, and in it Captain Ibbetson alluded to the experiments of Professor Gerber, of Berne, who, it is said, had for many years been endeavouring in vain to find some mode of rendering permanent the pictures which it was known to chemists the sun was capable of producing. The inference seems to be that Gerber had obtained some sort of results (impermanent) before Talbot's work became known.

It is curious, too, to notice how fashion from the very first days has swung pendulum-like from end to end of her arc.

We have had our periods of cold and warm tones in prints, and here we find the reviewer in the "Athenæum" writing of certain prints:—"There is a peculiarity, however, in these productions which we think might be advantageously avoided. The colour is a beautiful light grey, and the tint is unusually smooth; but they have rather the appearance of lithographs, and are not to the eye so pleasing as the warm sepia tint seen in many excellent specimens around them."

Adieu.

With this week's "History" the writer of the series of notes which have appeared regularly during this year must conclude his tales of the old days. Their recapitulation has been a not unpleasant task, and "Historicus" has been gratified to learn that others—not many, perhaps, but a few—have shared with him his experiences in looking back on much that has long been forgotten. "Look for the future in the past" is the dictum in so many words of one eminent historian. Progress makes strange turns and windings in its course, and perhaps these weekly doses of history have opened the eyes of some readers to the many things in photography which have been discovered over and over again, and will, no doubt, continue to be invented and patented. Thus it is to be hoped that even those whose boast is of the present may have found that we of the old school had something to teach them. They on the eastern side of life's meridian may see fruits of progress which we have never hoped for, but an old writer, who has also worked and watched, may perhaps be allowed to say that they will never see again the old enthusiasm which fired photographers of forty or fifty years ago. The present writer has only gathered a few scattered threads and brought them together. Yet he hopes that should ever a history of photography be written in English his few chapters may aid the author in his task.

HISTORICUS.

A PROPOSED COPYRIGHT BILL.

[Proposals to amend the present law of copyright have been understood to have been in contemplation for some time past by the Artistic Copyright Society, a body composed chiefly of artists and including only one representative of photographic interests on its general committee. The draft of a Bill has now been drawn up, and is at present being discussed by persons interested. We shall refer in detail in an early issue to the provisions as they affect photographers, but we will now content ourselves with quoting the clauses which are specific alterations of the present copyright law.—Eds. B.J.P.]

THE copyright conferred by this Act shall endure for the following terms:—

(a) In the case of an original work of fine art, for the life of the author and until the expiration of thirty years after the end of the year in which he died.

(b) In the case of one work of fine art, made by one person from any work of fine art designed by another, of a cast from nature, and of a photograph, for a term commencing on the completion of such work, cast, or photograph, and continuing until the expiration of thirty years after the end of the year in which the same shall have been completed.

* * * * *

In case any work, the subject of copyright under this Act, shall be a portrait made on the request of any person for pecuniary consideration, the copyright in such portrait shall,

on payment of the consideration and in the absence of agreement in writing to the contrary, belong to such person. But this shall not extend to a work of sculpture intended for a place or a building of a public nature.

* * * * *

Except as in this Act provided, the right of first publication and the copyright in any work, the subject of this Act, shall remain in the author, whether such work be sold or disposed of by such author or not, unless the right to publish the work or the copyright therein be expressly assigned or disposed of in writing by him; or pass by operation, or devolution of law, or testamentary disposition.

* * * * *

In regard to the register of copyrights it is provided that the officer at Stationers' Hall shall make, and keep full indexes of all entries made under this Act, arranged alphabetically, so as to show (a) the title or description of the work; (b) the name of the author, and (c) the name of the proprietor, with reference to the place in the register where the full particulars of registration may be found.

* * * * *

Before delivery on sale, or for hire, or exhibition, of any copies of a work, the subject of copyright under this Act, the persons publishing such copies shall cause every such copy to be marked as follows:—

(a) In the case of a reproduction of an original work of fine

art, which has copyright under this Act, with the author's name and the words "author's copyright."

(b) In the case of the reproduction of any other work, with the name of the proprietor of the copyright and year of the completion of the work, together with a notification that the said work is copyright. And if he fails to do so, no action shall be sustainable nor any penalty be recoverable by the proprietor of the copyright in respect of any copies of such work made in good faith by other persons unless the proprietor shows that he took proper steps to secure the marking of all copies issued by him.

And any person who shall falsely mark or cause to be falsely marked any copy of a work requiring to be marked under the previous sub-section shall be guilty of an indictable misdemeanour and shall in addition be liable at the suit of any

party aggrieved to a penalty not exceeding ten pounds for every such offence.

* * * * *

An agent duly authorised in writing may do for an author or proprietor of copyright any act required or authorised by this Act to be done by him and every act so done shall be as effectual for all purposes of this Act as if done personally by such author or proprietor.

* * * * *

"Copy" shall include a reproduction of any other work of fine art or photograph by a sculpture or of a sculpture by any other work of fine art or photograph.

(c) A representation of any work by a living picture or by any other means whereby the design of the work is reproduced.

ORTHOCHROMATICS AND OTHER MATTERS.

[An abstract of an address to the members of the Croydon Camera Club on December 13.]

A most instructive and interesting address, mainly on some important points arising on orthochromatics, was delivered by Mr. C. E. Kenneth Mees on the 13th inst., Mr. A. J. Newton kindly and most materially assisting towards the subject matter of the evening.

The Blessed Word, "Practical."

Mr. Mees first had a tilt against the ubiquitous individual, who loses no opportunity of referring to practical and theoretical workers, with a decided and invariable expression of opinion in favour of the former. If a man, said Mr. Mees, takes a series of photographs of, say a landscape, of complex shades and colours on plates of approximately unknown speed, in a light which can only be gauged in the roughest manner, and subsequently develops the plates just as long as it pleases him, in a developer of uncertain composition, then the test so applied was called "practical," and the operator "a practical man." Such a test could not hope to show small differences—which might exist, have an important bearing, and yet pass unnoticed. On the other hand, a tester of plates, who worked under fixed and invariable conditions, including a standard light, exact exposure, and with measuring instruments of the utmost precision, which would infallibly detect minute differences, if they existed, was promptly labelled a "theorist," and the tests "mere laboratory experiments." He did not share this conclusion. He did not mean to suggest that all photographic investigations involved expensive and elaborate apparatus; as an instance, there was one piece of work in particular which anyone might profitably take up.

Suggested Experiments—Slow Plates for High-speed Photography.

In some of his earlier investigations he had found that for high-speed focal-plane work, necessitating under-exposure, it by no means followed that a plate of high H and D number necessarily gave a better rendering than one of lesser number. He suggested trial exposures might be made behind a transparency to a standard light, on plates of varying rapidities and development properties. The exposure, which should be the same for all, should be cut down to the lowest possible limit consistent with obtaining a printable negative on the best plate. He thought such an investigation might show that for extreme speed work a plate of medium rapidity would produce better all-round results than one of the ultra-fast brands. This might be partly due to the slower plate standing more prolonged forcing in development. Should any of his fellow-members present be willing to undertake such a series of experiments, he would be pleased to discuss the necessary precautions to be taken.

The New Orthochromatism.

The lecturer then passed on to a consideration of the properties of light, and its carrying media the "ether," and the analogy between

light and sound. Diffraction phenomena were also dealt with and explained. Finally, turning to the main subject of the evening, Mr. Mees said that orthochromatics had, no doubt, advanced considerably of late. The earliest sensitisers, such as eosine and erythrosine, sensitised comparatively feebly, and not at all into the red. Cyanine had increased sensitiveness to red, but lowered the quality of the plate, being not alone in this respect. The introduction by Dr. Miethe of the iso-cyanines was as much an advance on their prototypes as the earlier orthochromatic plates were on ordinary plates. In the iso-cyanine group, pinachrom, pinaverdol, and lastly, but by no means least, pinacyanol, should be mentioned. Pinacyanol gave an enormous extension into the red. Using a bathed pinacyanol plate in conjunction with an adjusted light-filter, or screen, a practically perfect rendering of the spectrum, right into the red, was obtainable. The speed of such a plate with the light-filter in position might correspond to a plate of 80 H and D without a screen. He need hardly point out the advance this represented, particularly in facilitating three-colour work.

The Properties of Commercial and Uncommercial Plates.

Hitherto no commercial panchromatic plates were really sensitive to the red, when behind the red screen in the tri-colour photography they relied mainly on some of the green and yellow, which the commercial screens invariably transmitted. The ratio of sensitiveness of such plates to red and blue might be roughly taken as 1,000 to 1. Even with the latest sensitisers a bathed plate was superior in the proportion of 5:1 to a plate in which the dye was added to the emulsion in course of manufacture.

Tests of Orthochromatic Plates.

When examining a plate for its colour-sensitiveness, the only test of real utility was to photograph the spectrum: a diffraction grating, which gave a normal spectrum in proportion to wave length, being preferred by the speaker. The over-lap which occurred could be neutralised by suitable screens. It was of the utmost importance that the source of light should closely approximate to daylight in composition if the measurements were to be of any use to the practical worker. Such an apparently white light as acetylene in comparison with daylight emitted ten times more yellow than blue, and if used for the purpose the plate might appear ten times more sensitive to the yellow than was actually the case. It followed from this that the majority of curves given in the text-books were, to say the least, misleading. He had overcome the difficulty by employing an acetylene light with a light-blue filter in front. Provided complete correction into the red was not required—as when testing ordinary ortho' plates—a dyed film met the case sufficiently well, but

for absolute accuracy, liquid filters had to be used. With these he had obtained complete correction from B to 3,700. He also measured the total colour sensitiveness of a plate by means of Dr. Eder's blue and yellow screens, and in the case of panchromatic plates measured a three-colour ratio through screens cutting at 6,000 and at 5,000.

A Demonstration of Colour-Sensitiveness.

Mr. A. J. Newton, by means of the lantern and interposed grating, then showed a series of tests of colour-sensitiveness of undyed wet-collodion, process, ordinary, and rapid plates, and the earlier and later English and American orthochromatic plates, also bathed gelatine, and dyed collodion plates. Nothing would have been more conclusive as to the relative value of the various plates and brands, thus brought under critical analysis, and the great advances recently made towards the perfection of orthochromatism. The ingenious

method adopted by Mr. Newton, in conjunction with Mr. A. J. Bull, for the projection of the tests, consisted, in the first place, in photographing the spectrum, the plates being exposed in proportion to their varying ascertained speeds. Transparencies from the resulting negatives were then made. These, when placed in the lantern, and in line with the grating, let through, so to speak, the exact colours the negatives originally saw and retained.

To fulfil the last condition absolutely, Mr. Newton said, the light used for taking the spectrum would have to be screened, but for judging the relative sensitiveness this was not necessary. In answer to a question, he also said that a reduced sensitiveness to blue did not necessarily indicate a corresponding general loss of speed. In some cases the dye might in effect form a screen or light-filter, and reduce sensitiveness, or something might be added to the dye with the same end in view.

FOREIGN NOTES AND NEWS.

Fine-Grained Emulsions.

M. GUILLEMINOT, in speaking before the International Union of French Societies of some emulsions with very fine grain which can now be obtained commercially, ascribes to them some properties which signalise them among the ordinary makes. With these plates it is possible to obtain clear and sharp images of objects of one-thousandth of an inch in length, about 1-250th of an inch being the limit with ordinary grained plates. The new plates also require much longer exposure to produce reversal, the actual increase being six times—that is, 150,000 times normal exposure. The gradation is also much better, and when orthochromatised the rendering of colours is much improved, and the results are such as have only been hitherto attainable with collodion emulsions.

An Improvement in Printing-out Papers.

In the current number of the "Photographisches Wochenblatt" there appears a communication from MM. A. and L. Lumière in regard to a manufacture of theirs which, whilst protected by patent, is of sufficient importance to warrant its being recorded. It is pointed out that the vehicle for the silver salts, whether collodion, albumen, caseine, or gelatine, and even the cellulose of the paper itself, will in a short time reduce the soluble silver salts, such as the citrate, lactate, nitrate, etc. This reduction is favoured by heat and damp, and even the most careful method of packing will not prevent it. The presence of these free silver salts requires an absolutely pure paper—one especially free from metallic particles—and, notwithstanding the great advances in the manufacture of the raw papers, this trouble cannot be entirely obviated. Silver stains on negatives and brown stains on the prints due to the accidental contact of hypo, and the comparative insensitiveness and want of correct gradation are also due to the free silver. The authors have endeavoured to find some substances which would hasten the reduction of silver chloride, and they find that whilst the animes do so to some slight extent, the phenols are much more active, and especially the di- and tri-phenols. It is, of course, well known that certain metallic salts have the same effect, such as the proto-salts of manganese, the nitrates and the arsenites. All these reducing substances can be used in emulsions in which the by-products of the formation of silver chloride are present, or in washed emulsions which only contain pure silver chloride; also in emulsions in which the vehicle is either gelatine, collodion, caseine, albumen, or other colloid. The most useful of all these substances appears to be resorcin, and a special paper has been patented in which there is no free or soluble silver salt which is obviously free from all the defects enumerated at the commencement of this note,

and which is far more sensitive than the ordinary P.O.P., and can be treated with any of the usual baths.

The Improvement of Defective Negatives.

Dr. Hauberisser suggests in "Photographische Korrespondenz" the following method for improving negatives which have been too much reduced in an ammonium persulphate bath. After thorough washing the negative is treated with a physical developer, such as the following, first suggested by Wellington:—

Ammonium sulphocyanide	120 grains.
Silver nitrate.....	20 grains.
Sodium sulphite	120 grains.
Hypo	25 grains
Potassium bromide	3 grains.
Distilled water	1 ounce.

One part of this solution should be diluted with 9 parts of water, and then 2 parts of rodinal or concentrated edinol developer added, and the plate flooded with the mixture, in daylight, and left until sufficiently dense. One may be possibly permitted to point out that as this physical redevelopment takes some three to four hours, it would be more reasonable to exercise a little greater care whilst the ammonium persulphate is in use, and arrest its action with a sodium sulphite bath.

Marginal Fog.

This defect is not often encountered at the present time, but it is occasionally met with in stale plates. It has been chiefly ascribed to unequal drying of the plates after coating or to the insufficient washing of the emulsion. Dr. Homolka, in the "Korrespondenz," details the results of his experiments extending over two years, and whilst possibly they are of more interest to the emulsion maker than the user of plates, they are of sufficient importance to be recorded. An emulsion prepared according to the ammonio-nitrate method with 3 per cent. of iodide was used throughout. When carefully washed with distilled water, so as to free it from all soluble haloids, plates coated with the same showed, after six weeks, strong marginal fog and distinct general fog. If to the perfectly-washed emulsion 0.02 per cent. of potassium bromide was added before coating, the plates showed in about three months strong marginal fog, but otherwise worked absolutely clean for two years. If plates, coated with the thoroughly washed emulsion and dried, were bathed in a 0.01 per cent. solution of potassium bromide, and again dried, they showed, after two years, neither marginal nor general fog. There is nothing new in the observation that a bromide keeps a plate free from fog, but the difference of action of bathing in bromide or addition of bromide to the emulsion is worth noting. These results were con-

firmed by the use of sodium nitrite. It is a well-known fact that a plate bathed for 2-3 minutes in a 1 to 2 per cent. solution of nitrite rapidly darkens on exposure to light (B.J., 1887, p. 423). Homolka finds that if a plate be bathed with nitrite it darkens equally all over, but that if to the thoroughly washed emulsion 0.02 per cent. of nitrite be added, and the plate then coated and dried and exposed to light, it will darken with the exception of a margin of about 10 mm. width. From this he concludes that the margins contain no nitrate, and that as the edges dry first, there is a diffusion of the soluble nitrite from the drying edges towards the centre, which is still moist and gelatinous. His explanation of the non-appearance of this diffusion, when the coated plate is bathed in nitrite, is that the emulsion takes up so little water, that it never becomes gelatinous, that is, it is merely gelatine *plus* water, and not an actual jelly. This experiment is confirmed by bathing a coated plate in a 0.01 per cent. solution of bromide, exposing to light, and then developing: it will blacken all over without showing marginal fog, but if the bromide be added to the emulsion, and the latter then coated, dried and exposed, strong marginal fog is seen, and it develops before the centre, where, according to Homolka's theory, there should be more soluble bromide. Although these experiments were carried out with an ammoniacal emulsion, precisely the same results were obtained with an acid boiled emulsion, though plates prepared with the latter were less prone to marginal fog. As, however, the latter plates were less than half the speed of the ammonia plates, some allowance must be made for this difference.

ILFORD, LIMITED.

A YEAR OF RECORD SALES AND INCREASED DISCOUNTS.

The ninth ordinary general meeting of the shareholders of Ilford, Limited, was held on December 12, at Winchester House, Old Broad Street, E.C., Mr. James Kemp-Welch (chairman of the company) presiding.

The Secretary (Mr. J. D. Robertson) read the notice convening the meeting and the auditors' report.

The Chairman said: In rising to move the adoption of the report and balance-sheet I may at once say that, though the directors much regret having to propose a smaller dividend on the ordinary shares of the company than was paid last year, they do not feel in the least discouraged, and have the greatest confidence that the report will meet with the approval and support of the shareholders. (Hear, hear.) As stated, the sales during the year just ended, notwithstanding the keenest competition, have been the largest ever effected since the company was formed, and tend to show that our position in the leading ranks of the photographic trade is as firmly established as ever, and that it is not unreasonable to expect a steady improvement in the future. With regard to the increase in discounts, which was dealt with at the last meeting, the keen competition and cutting have compelled the directors in some instances to still further increase the high rates already fixed upon, in order to enable them to compete on equal terms with other manufacturers. Now the success of an enterprise such as ours depends on the following considerations: The cost of production, the volume of sales, the ratio between the cost and the prices obtained, and the cost of administration. The cost of production during the past year has been higher than usual, owing to an increase in the price of two important materials—silver and glass; the latter due to a strike among the Belgian operatives, followed by an advance in British manufactured goods. The strike is now at an end, and we may expect easier rates in the near future; but, while the cost of production has increased, the net return of the sales has been diminished by the higher scale of discounts ruling throughout the year. Notwithstanding these adverse circumstances, the net result of our trading for the year is an increase in the profit

of £1,076 as compared with 1904. Had the average discounts been the same in 1905 as in 1904, this amount would have been very considerably increased. Last year, as you may remember, higher discounts were in force for the last seven and a half months only. Should the increase in our sales continue at the same rate, there is no reason to doubt that the improvement in the profit, which has already begun to show itself, will be more marked. The prosperity of a business like ours must ultimately depend on the confidence of the public in the high quality of our productions, and our utmost efforts must be directed to keep the confidence which, I am happy to think, we now possess, thanks to the untiring efforts of our managing director and staff. (Applause.) To obtain the best result from their efforts, no expense should be spared to keep our factories and machinery in the highest state of efficiency, and, with this end in view, we have not hesitated to make additions to our plant, which accounts for the greater part of the increase appearing in the accounts under the head of freehold land, building, and plant. We believe that these additions will eventually result in considerable economy. The Warley factory has been in use throughout the year, and has in all respects justified the expectations expressed by the managing director in 1903. Had it not been for the facilities afforded by the new factory, it would have been impossible for us to have coped with the large increase of trade to which I have alluded. We are now in a position to deal efficiently with the business we possess and to welcome, without any fear of being hampered for room any further increase which the future may bring us.

The cottages at Warley, to which reference was made last year, are all occupied, and, besides providing comfortable dwellings for our men, yield a fair return on the capital expended in their erection, after allowing for repairs. Many of you, no doubt, visited our exhibition of prize photographs at the Modern Gallery, New Bond Street, in July. As you know, we offered prizes amounting to £750 for work done with Ilford plates, paper, etc. The result was we received from all parts of the world many beautiful and artistic photographs. This competition has already had a favourable effect on our trade, and the collection is being exhibited in other parts of the country. Turning to the accounts, on the right hand side, in accordance with the resolution passed at the last annual meeting, £5,000 was written off goodwill, leaving the amount £230,000, and our proposal is now to apply to the reduction of this item £4,000 out of the profits of last year. Freehold land and plant show a net increase of £5,855 5s. 6d., to which I have already referred. Depreciation written off amounts to £1,732 10s. 2d., or £337 more. I may remark that this depreciation is worked out on a fixed principle, without any reference to the profits of the year. Since 1896, when the company was formed, the sum of £17,283 has been written off under this head. Investments and cash, which should be taken together, show a decrease of £6,407 17s. 4d., accounted for by the increased expenditure on capital account. Sundry debtors are within a few pounds the same as last year. This reflects great credit on our commercial manager, considering the much larger business done. Stock, which is taken at prime cost, shows no material alteration. On the other side capital remains the same, and creditors are £2,238 less. In the profit and loss account the profit on trading account is £3,419 more. On the other side salaries, advertising, rates, etc., mark an increase of £2,397. The greater part of this is accounted for by advertising, in which I include the cost of the competition and exhibition. I should say that the trading expenses include the amount of rewards, which formerly, in the shape of bonus, was paid out of the profits of the year. Bad debts, for which £300 was provided, amount to £7 19s. 4d., and legal expenses show a reduction of £280 4s. 9d. Here I may remark that the action against Westendorp and Wehner for imitation of the company's labels—to which I referred last year—has, on appeal, been decided in our favour on all

points, and the damages and costs have been paid. (Applause.) I have now pleasure to announce that, with a view to strengthening the board, the directors have elected Lieutenant-Colonel Ivor Philipps, D.S.O., as a director of the company. I feel that this election will give general satisfaction, and I shall presently ask you to confirm it. In conclusion, I wish to acknowledge our indebtedness to the managing director and his staff. They are keenly alive to every production that makes its appearance in photography, never rest on their oars, but are always on the alert. May success attend their efforts. (Loud applause.)

SIDELIGHTS ON THE FREE PORTRAIT BUSINESS.

A CASE came before the Cambridge Police Court last week which is an interesting commentary on the methods of firms running the "free portrait" business. The prosecutor, who failed to appear, was stated to be Alfred Margand, trading as the Crown Art Co., a firm which our readers may recollect was the subject of some forcible comments from *Truth*, quoted in our issue of July 28 last.

At the Cambridge Borough Police Court James McBirnie, aged 23, described as an agent, of 1A, Hertset Road, Seven Sisters Road, London, was charged with embezzling the sum of 4s. 6d., received by him while in the employ of Alfred Margand.—At the outset of the case the prosecuting solicitor, Mr. A. J. Lyon, asked for a remand for a week on the ground that the prosecutor had not yet been informed of the arrest.—The allegation against the prisoner was that while acting as a traveller for the prosecutor he collected 4s. 6d. from a person named in the indictment and gave a receipt, but did not include the amount in the return he made to the prosecutor. The money, said Mr. Lyon, had not been accounted for, and there were two other cases for hearing.—Evidence as to the arrest having been given, Mr. Morton A. Jones (of Messrs. Crook, Milns, and Jones, Cheapside, London) was heard for the defence. After maintaining that there had been plenty of time to communicate with the prosecutor, Mr. Jones proceeded to make a statement, which, he said, he should be willing to give on oath. He had had a good deal to do with the prosecutor during the last four years. Prosecutor, who was a Polish Jew, was first brought to his knowledge in 1902, in connection with a prosecution of a man named Howard for embezzlement at Basingstoke. Howard, who was a traveller and collector, was arrested at Finchley under circumstances similar to those in this case, and was taken to Basingstoke. Prosecutor did not appear, and a remand was granted, the charge being eventually dismissed. Subsequently he (Mr. Jones), on behalf of Howard, issued a writ for libel against Margand, the latter having circulated leaflets stating that Howard had been dismissed for embezzlement. One hundred and fifty pounds damages were awarded to Howard, but not a penny of that had been received, Margand's wife claiming all the goods when an execution was levied. An interpleader case was begun, and referred to the Master of the Rolls. Coming to the present case, Mr. Jones said McBirnie left the prosecutor's service on November 26, about the time of the levying of the execution. He did so because he was unable to get his wages, and he wrote and told Margand that unless the wages were paid by a certain time information would be given to the opposition solicitor as to who was carrying on the business. Later on, McBirnie and a man of the name of Mitchell volunteered to give evidence in the case against Margand, but Mitchell, who seemed a vacillating sort of person, disappeared. Mr. Jones said his point was that Margand had an object in getting the accused out of the way. On the interpleader coming before the High Court Margand did not appear to support his wife's claim, but the accused, who wanted to get back to Scotland, had his evidence taken, and was cross-examined. The information in the embezzlement charge was laid after the prosecutor knew that McBirnie

was to give evidence.—Mr. Jones having repeated in the witness-box the substance of his statement, the Bench dismissed the case, with costs, it being pointed out to them that the question would be gone into on the further hearing of the interpleader.

Photo-Mechanical Notes.

Sensitive Solution for Line Printing.

BICHROMATED albumen is usually used for this, but eggs are sometimes difficult to get, and it is more or less troublesome to prepare their albumen for the solution. The albumen may, however, be entirely replaced by fish-glue, providing a sufficiently small quantity is taken. A good formula is:—

Ammonium bichromate	1 ounce.
Le Page's fish-glue	5 ounces.
Water	100 ounces.
Ammonia, .88	5 drops.

The treatment is exactly the same as for albumen solution. The exposure will be found to be at least as short, and the rolling-up with photo transfer ink and development will, if anything, be easier.

A. J. N.

Pure v. Impure Zinc.

In 1900 ("Phot. Korresp.," July), Herr Novak, of the famous Viennese School of Photography, examined some commercial zincs as to the suitability for etching and burning-in, and has continued his researches, which are now published as a separate reprint from the "Zeitschrift für Anorganische Chemie," with numerous tables and photomicrographs. The final conclusions which he comes to are as follows:—That a small addition of cadmium, up to 0.25 per cent., gives, after rolling and heating, a finer granular structure than zinc free from cadmium, that the hardness and coherence are increased, and liability of the zinc to fracture decreased. An increase in the proportion of cadmium above 0.5 per cent. has, however, the opposite effect. Variation in the amount of lead between 0.5 and 2 per cent. has no influence on its rate of solution in dilute acids, whilst the admixture of cadmium slightly shows the same.

A Photo-Engraver's Copyboard.

A new form of copyboard has been placed on the American market by The Hamilton Manufacturing Company. According to the description in the "Inland Printer," it takes the form of copyboards

Section of Photo-Engravers' Copyboard.

arranged so that they will hold any size of copy, from a postage stamp to within one-half inch of full size of board. The company claims that groups can be arranged in any desired position and changed at will until the desired effect is secured, without mutilating

the picture or the board. No tacks, nails, or pins are required. The copy is held by means of springs clamping the edges. The springs are wedged into position by means of a lever or clutch. A stiff, warped copy is held perfectly flat in any desired position without more trouble or effort than is required with flat copy. It will hold any thickness of copy, from tissue paper to three-eighths-inch in thickness. Even a book can be held in place by clamping the covers and opening the page to be reproduced. The pages can be held down by means of strings, secured by springs, and run across the margin of the page. If desired, a plate glass can be laid over copy and supported by the springs, if the glass is not over three-eighths-inch in thickness. The grooves in the board are spaced two inches apart from centre to centre in both directions. In enlarging or reducing copy, the reflection of the grooves on the ground glass can be measured, and the desired proportion secured. For instance, if the operator desires to reduce copy one-half, the camera is adjusted until the grooves on the board measure one inch, and if an enlargement twice the size of the original is to be made, the camera is adjusted until the grooves on the board measure on the ground glass four inches. In this way any desired proportion, either larger or smaller than original, can be secured. There is a degree scale drawn in one corner of the board, with perpendicular, horizontal and quartering lines, which are marked by variations of ten degrees. This is an important feature and enables the operator to locate the centre, and he can break the pattern in reproducing the half-tone. This is an important feature also for three-colour work, as any operator will understand.

The Kroll Etching Machine.

Robert C. Kroll, St. Louis, is the inventor of a machine, the novel features of which will be seen from the following account by the inventor in the "Inland Printer":—"To begin with, my machine is built on the long-approved principle of an oscillating tub. It has a perfectly adjustable rocking device, enabling the operator to adjust the stroke of the tub to any depth desired; an exhaust to get rid of the acid fumes completely, and a system of perfect lighting of the plate during etching. From the front view of the machine you will notice that my tub has inclined splash-boards, thus blocking out

little or no light when the machine is placed in a position to receive its natural light from either side. Over the tub is a hood having glass windows at the sides and a large glass door on the top, through which the etching procedure can be watched. At the front the hood has a large opening, allowing the operator's arms free access to any part of the tub, the hood being high enough to permit freely brushing any part of the etching surface. The air chamber at rear of tub is part of the tub, and by means of a tubular journal rocks on a stationary air

tube behind it, thus forming the rear pivot. The front pivot is on the same axis, exactly opposite, also hollow, but only large enough to admit a water pipe. These journals are made of a special composition metal which is non-corrosive. The machinery is on a platform under the tub and consists of a suction blower and a rocking device, driven by a one-sixth horsepower motor, using three-quarters of an ampere of current put in operation by a button. The power shaft of the motor has the blower at one end and a worm-wheel at the other.

This worm-wheel runs a speed-reducer attached to a countershaft. At the near end of this shaft is a crank wheel which is connected by a driving rod. The driving rod is connected by a set-screw to the crank wheel. The set-screw moves in a slot by which any speed desired can be given to the rocking of the tub. By turning a lever water is turned into the tub, and by pulling out the glass stopper the used-up etching solution is allowed to flow through a flexible rubber hose to the sewer. Electric lights within the hood at either side light the work perfectly. The machine is 4 ft. high and 39 in. across."

Patent News.

Process patents—applications and specifications—are treated in Photo-Mechanical Notes."

The following applications for patents were made between December 4 and 9:—

ENVELOPE.—No. 25,197. A combined frame and envelope for holding and displaying photographs. Andrew Meldrum, 41, Reform Street, Dundee.

PRINTING FRAME.—No. 25,215. Improved photographic printing frame for multiple or combination printing. William Graham Brown, Cordiner United Free Church Manse, Lesmahagow, Lanarkshire.

SHUTTERS.—No. 25,237. Improvements in photographic shutters. Conrad Beck and Horace Courthope Beck, 23, Chancery Lane, London.

NEGATIVE BOXES.—No. 25,276. Improvements in negative boxes. William Frederic Butcher, 322, High Holborn, London.

STUDIO LIGHT.—No. 25,392. Improved apparatus for illuminating photographic studios with electric incandescent lamps. Philp

Georg Von der Lippe, Birkbeck Bank Chambers, Southampton Buildings, Chancery Lane, London.

COPYING APPARATUS.—No. 25,492. Improvements in photo-printing apparatus. Leonard Shaw, Clu: House, Surrey Street, Strand, London.

FOCUSsing.—No. 25,515. Photographic focuser. James Preston Cribb, 127, Chichester Road, North End, Portsmouth.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

PIGMENT PAPER.—No. 9,324, 1905. The claim is for a sensitising solution of potass. bichromate containing acetone, the presence of which is to cause rapid drying of the tissue. The sensitising solution is prepared and used in such a way as the two following:—(1) 8 parts of ammonium bichromate are dissolved in 100 parts (by weight) of water, and this solution is mixed with 150 parts (by weight) of acetone. This liquid is applied for the purpose of sensitising a carbon tissue by spreading it over the tissue by means of wadding. After 5–10 minutes, according to the moisture of the atmosphere, the tissue is dry and is exposed to light under the negative, a copy of which is to be taken. The further procedure is that well known, the exposed tissue being washed at ordinary temperature with water, which process is shorter than when the tissue has been sensitised by plunging it into a bichromate solution. The carbon tissue is afterwards transferred, then developed by treating it with warm water (40–50deg. C.) and finished in the usual manner. A carbon print thus obtained shows very clear whites and is well shaded. (2) For sensitising, for instance, a paper covered with a layer of gum incorporated with a pigment, as in the gum-bichromate process, there may be used a mixture of 2 parts of potassium bichromate, dissolved in 40 parts of water, with 60 parts of acetone. The sensitising process is then carried out by applying this solution to the layer either by means of a suitable brush or by plunging the paper into the solution. In the latter case the tissue will dry in $\frac{1}{2}$ –1 hour, whereafter it is exposed and finished as above indicated. The copy thus obtained has also very clear whites and is well shaded. The invention is also applicable to layers of sugar incorporated with a pigment. C. D. Abel (for the Actien Gesellschaft für Actien Fabrikation), Birkbeck Bank Chambers, Southampton Buildings, London.

PRISMS IN LENSES.—No. 322, 1905. The object of the invention is to produce "lens and prism-combinations in which, wedge-shaped prisms are placed between lenses, and by this optical device effect to form: one, two, or three photographic picture-records in an adapted-focussing plane." In the specification it is stated to be intended for two-colour and three-colour photography, and for cinematographic projection. Reference is made to Dr. Jumeauix's patents (wrongly printed "Tumeaux" in the specification), and to those of Captain Davidson. The following extract will show the idea of the inventor:—"If a prism is placed in the front, centre, or back of an image-forming lens, or lens combination, the image is deflected. Now, on account of the combined actions of prisms and lens, resulting in deflection, inversion, reversion, and spectral aberration, it is only a matter of natural consequence, that the formed picture will show signs of unsharpness and of distortion. The defects of the combination show least when the prisms are placed at or near the crossing-point of the light rays, that is, near the optical centre of the lens combination, giving then the smallest angle of deviation, reversion, dispersion, etc., and therefore the defects of distortion and unsharpness will be

smallest and scarcely noticeable. I may also point out, that the longer the focus of the lens, the narrower is the angle of the prism required; that is, if the lens combination, including the prisms, is giving a half inch dispersion, separation of pictures, in four inch focus, then the defect will be 2 by 2 if the distance is only two inches, and the same half-inch dispersion and separation is required at the focussing point. If prisms are used at the back or front of a photographic lens, and it is desirable to transform the same into the lens and prism combination, then a single lens, or a combination of lenses, can precede or follow the prisms, so as to bring the prisms between lenses. This addition is also a help to correct miscalculations in the lens and prism combination. The adding of an extra lens will naturally shorten or lengthen the focus, and enlarge or reduce the size of picture. Several drawings of possible between-lens arrangements of prisms are given, of which those reproduced show (1) position of prisms for "pictures in two-plane;" (2) position of prisms to give three pictures in one plane. R. Y. B. stand for the light rays, red, yellow, and blue (coming from one optical view) which are afterwards sorted out by the colour-filters (screens) R-e, or Y-e, and B-e, and give then the necessary colour-

Fig. 1.

Fig. 2.

records for photography in colours by the subtractive (printing), or additive (transparency) methods. By this device of lens and prism-combination, all the pictures are rendered, with the aid of one frontal-lens combination, from one point of view only, and by the aid of the same device, in reversing the order of passing the light rays, the two or three photographic records, are naturally reconstructing one picture." Otto Pfenniger, 105, Hythe Road, Brighton.

INCREASING BRILLIANCY OF IMAGES.—No. 29,561. The invention consists of (1) the use of intentional artificial means of tarnishing polished glass lenses as nearly as possible to the darkest brownish slate colour, either by immersion in suitable chemical solution or in gaseous reagent or by intimate contact with more solid substances of suitable nature, whereby the light transmitting power of such lenses is enhanced and their light-scattering power correspondingly reduced, thus leading to the greater brilliancy of the final images formed by such lenses; and (2) the use, for tarnishing freshly polished lenses of densest baryta crown glasses, or the densest baryta flint glass of the dilute solution of ammonium hydrosulphide and nitric acid. Let it be supposed that a photographic lens is composed of six separated lenses, four

having a refractive index for the blue rays of 1.62, and two having a refractive index of 1.54. Then it can be shown by a formula that the intensity of the light after passing through the 12 polished surfaces will be reduced to 52 per cent. of its original intensity, the other forty eight per cent. being partly reflected back and lost and partly re-reflected back in more or less complex ways on to the photographic plate, and there causing a general milkiness of the image. This cumulative loss of light by numerous surfaces, together with the milkiness of the image owing to re-reflections, constitutes a very serious drawback to the use of more than three or four separated lenses in any optical combination. The amount of light lost in this way generally far exceeds the loss of light due to the absorption consequent upon the thickness of the lenses. At the same time it can be shown that the very finest and angularly extensive images to be yielded by photographic and other lenses, cannot be obtained without the use of more than 4 lenses, while combinations of 6 or even 8 hold out prospects of yielding images of great perfection, provided that the very serious drawback of the large proportion of light lost or scattered by reflections and inter-reflections from the surfaces can be got rid of, or at least very much reduced, and thus the brilliancy of the final image as it is termed, formed by such lens system, be substantially increased. The essence of my invention is to bring about this very desirable result by the artificial and intentional tarnishing of the polished surfaces of the lenses. I find that if the freshly polished surfaces of dense barium crown glass are tarnished in an aqueous solution of sulphuretted hydrogen, until by reflection they assume a brownish slate colour, then I estimate that the amount of light reflected is reduced to about 40 per cent., or perhaps to only one-third. That is in place of the 5.5 per cent. reflected off a newly polished surface, I then get only about 2 to 2½ per cent., while the transparency of each surface is increased from 94.5 per cent. to 97.5 per cent. Supposing this great diminution in reflective power by tarnishing to 40 per cent. is carried out for all 12 surfaces of the above-mentioned six lens combination, then instead of only 52 per cent. of light transmitted we shall have 77½ per cent. transmitted, and instead of 48 per cent. wasted we shall have 22½ per cent. In fact a rather more brilliant image will be yielded by such a combination of six or even eight lenses tarnished than by a combination of only three lenses normally polished. It can be shown that the optical effects of polished spherical surfaces or their durability are in no ways interfered with by this tarnishing process, so long as it is not carried much beyond the stage when the brownish slate tint first appears. I find that dense barium crown glasses which are used so largely for the positive lenses in modern combinations, can be tarnished by immersion in nitric acid diluted with at least four parts of water, or by immersion in an aqueous solution of sulphuretted hydrogen, or sometimes by sulphurous acid. My invention, while rendering the use of a larger number of lenses in combination possible, can equally well be applied to rendering more transparent already existing combinations whether of only two lenses or of a larger number, and thus the brilliancy of their images be increased. As a result of a large number of experiments, I have found that the various types of densest *baryta* crown glasses with refractive indices for the D ray varying between 1.57 and 1.62, such as are so largely used for the positive lenses of modern anastigmatic lenses for photography, etc., may be best tarnished by a few minutes immersion in the following solution:—Dissolve four fluid drachms of ammonium hydrosulphide in twenty ounces of water, and gradually add while stirring, two drachms of pure nitric acid, already diluted with four drachms of water. The amm. hydrosulphide consists of strongest liquid ammonia diluted

with twice its volume of water, and then saturated with sulphuretted hydrogen gas, after which a little extra ammonia is added for keeping purposes. The solution will, after the greater part of the acid has been added, change from alkaline to acid, upon which a precipitation of sulphur will take place. This should be allowed to settle, and the clear liquid be poured off for use. As variations may occur in the strength of different samples of ammonium hydrosulphide, it is as well to point out that unless the solution is distinctly acid in its reactions, the desired tarnishing effect will not take place. Any lenses to be tarnished should preferably be freshly polished and scrupulously clean, and may be held suspended in the solution, held in a closed vessel, in any desired number, at a time by means of a piece of wood or porcelain in which are fixed pairs of slender slips of lance-wood or other dense and springy wood, each pair of which will hold a lens nipped between two opposite points of its margin, thus leaving the polished surfaces perfectly open to the action of the liquid. During the immersion a little movement is desirable to prevent stagnation. Four minutes will be enough time for some glasses, but much longer for others. But it is always desirable to watch the progress of the operation, by taking out the lenses and wiping one of them dry on one surface, when the stage of development of the tarnishing will show itself. It should never be allowed to proceed beyond the dark brownish slate tint, and should be arrested by rinsing off with clean water. The progress is generally, first, from the bright polish to a dull grey slate colour, after which the desired dark brownish slate colour appears, the next stage is a dull blue shade, after which a brighter greenish sheen appears. Either of these colours, however, indicates that the process has gone too far, and it is better to stop short of the brownish slate colour rather than go too far towards the bluish tint. If the solution acts with inconvenient rapidity, then dilution with water should be resorted to, or if it proceeds too slowly, then often a less proportion of water in the mixing will be found to accelerate matters. I had hoped to be in a position to give directions for tarnishing ordinary dense flint glasses, but so far have not found any solution or process that can be depended upon to act within a reasonable time. It is certain that some sorts of yellow soap if allowed to dry upon a polished flint glass surface in the course of months' tarnish the surface to the desired tint, and I have got the same result by prolonged immersion in a thick solution of either yellow or soft soap, but not as yet with constant enough results for me to give a definite recipe. There are certain glasses, such as the lighter flints and silicate glasses, and the lighter and *baryta* light flints, which have not so far shown the slightest tendency to tarnish with any solutions or chemicals that I have yet tried, and it may be that it is quite impossible to tarnish them. But in modern photographic lens combinations densest *baryta* crown glasses with a refractive index as high as 1.61 are generally the most used, and it is therefore of the greatest importance to increase their light transmitting powers, whereby about 11 per cent. of light may be gained in the case of four surfaces. There is also a dense *baryta* flint now on the market with a refractive index of 1.657 for the D ray, which will take the requisite tarnish in the above solution as well as the glasses before named. Harold Dennis Taylor, Stancliffe Mount Villas, York.

A FILM SLIDE.—No. 28,863, 1904 This invention consists in the employment of a grooved sheath of aluminium or other material into which the photographic plate or film is inserted at the one end; the plate being protected by a cover consisting of a single sheet of light-proof cloth; the sheath with its protecting cover being inserted in the camera in the usual manner with this class of plate carrier. The sheath has the edges of the two

long sides, and the one end turned over, to receive the plate; but the two long sides have their turned over edges made double, the one or under groove being to receive the plate, and the other or upper groove being to receive the edge of the covering cloth. This simple arrangement dispenses with the necessity of an envelope such as is used in other plate-carrying devices of this class. The edge of the forward end of this single piece of covering cloth is stiffened so that this end of the cloth may be inserted within the upper groove of the sheath from the open end thereof, so that the cloth may be drawn along evenly over the face of the plate. The edge of the stiffened bar is brought under the turned-over edge at the end of the sheath. The other end of the piece of cloth has its edge turned over so as to form a narrow pocket to receive a projecting end of the plate of the sheath, and thus ensure no light having access between the piece of cloth and the photographic plate. The back of the stiffened bar of the piece of cloth is provided with two brass or other pins by means of which the covering cloth is drawn back from over the face of the photographic plate when it is desired to expose the plate in the camera. The inner side of this roller slide is provided near the end thereof with two small holes, so that when the slide is in its closed position, and the sheath is placed within the frame, the pins on the end of the covering cloth engage with the holes in the end of the rotating slide, so that when the slide is opened it carries along the covering cloth with it, the cloth doubling itself over the end of the frame similar to the doubling over of the slide itself. Robert and Matthew Ballantine, 101 and 107, Buchanan Street, Glasgow.

New Books.

"Geschichte der Photographie." By Dr. Josef Maria Eder. Halle: W. Knapp. M. 12.

Dr. Eder has at length brought forth his "History of Photography," and the copy before us, which apparently was completed in March last, is still another piece of proof of the ceaseless labour and untiring research by which he has enriched students of photography with a series of volumes, which, as technical literature, are not surpassed, so far as our reading goes, in any other science or branch of technology. The scheme of the history resembles that which other writers have found the best in recording the evolution of a science—Dr. Ernst von Meyer, for example, whose excellent "History of Chemistry" has been translated into English. Dr. Eder approaches his subject in no half-hearted way. He begins with Aristotle in the fourth century before Christ, and reviews the chemical and physical sciences which eventually gave birth to photography—in 1839, we may say. This review includes the history of the camera-obscura, of stereoscopic vision, and of the magic lantern. Dr. Eder still declares for Schulze (1727) as the first photographer, and repudiates the views of those such as the late Mr. Litchfield, who regard—and rightly, we think—Schulze's work as purely photo-chemical. But it is when we come to the year 1839 and the much-discussed work of Niepce, Talbot, Herschel, and Daguerre, that Dr. Eder, vulgarly speaking, "spreads" himself. He dwells closely on every part of the story of the two Frenchmen down to a quite superfluous congratulatory letter which the Austrian Government addressed to Daguerre. Yet Talbot and Herschel he treats in a very summary way. We should have thought that with eighty-four pages devoted to reproducing in full nearly all the documents relating to Daguerreotype, he might have spared more than eleven pages to photography on paper. In consistency, the not very lengthy papers of Talbot might have received equal prominence;

and actually we cannot find a report of the perfectly independent paper of Sir John Herschel on March 14, 1839. Dr. Eder does not appear to recognise the fact of Herschel's independent invention or discovery of a photographic process. His footnote on page 240 implies that Herschel added fixing with hyposulphite to Talbot's first process. Nor can we find that he credits Herschel with the preparation of the first negative on glass: he should reproduce the original now in the possession of Sir William Herschel. But, after all, these are not serious omissions from a volume which records the history of photography with a thoroughness never before attempted. Dr. Eder has our warmest congratulations. He has undertaken a duty involving peculiar difficulties, and the labour of his authorship is not to be measured by the 460 pages of the volume. The "History," we ought to make clear, is not confined to the early days of photography. The later chapters trace the development of the various branches of photography, such as orthochromatism, artificial light, printing processes, colour photography, etc., to the present time, though we notice the chapter on animated photographs stops short at the point—the introduction of the modern film cinematograph—where it becomes important.

To improve still further the "Wellcome Exposure Record and Diary" is admittedly the most difficult of tasks, and the 1906 edition of the Diary is a tacit admission on Messrs. Burroughs Wellcome's part that the many features of their pocket-book have reached a point of finality. For there is no distinct departure from last year's arrangement. The list of plate speeds has been revised to date, and now includes every important English, Continental, and American plate, and a number that are not important. As hitherto this list is used in conjunction with the exposure calculator. Each diary contains a circular of a prize competition for photographs suitable for reproduction as supplements in succeeding issues, in regard to which Messrs. Burroughs Wellcome punctiliously point out that the prize purchases only the right to reproduce in the "Diary," not the sole copyright. The Ex Libris of the Diary is a thing to be seen, not described, and we would also reassure those who may hastily judge from the illustration on p. 54 that their supply of "Tabloid" chemicals may be cut off by a City fire, that the artist's aim is merely to typify the light and learning which directs the manufacture of these highly pure photographic materials. Although there are two editions, as usual, one for the northern hemisphere and one for the tropics and southern hemisphere, the Diary for 1906 is issued in one style of binding only, art green canvas, and the price is 1s.

ART IN PHOTOGRAPHY.—A de luxe volume is announced for April 1st, from the press of the Photo-Club de Paris. MM. Demachy and Puyo are its joint authors, and the volume will treat of printing and other processes specially consecrated to artistic photography. Gum, ozotype, and carbon figure in the prospectus with platinotype and other processes. The work is to include 40 plate illustrations, characteristic of modern pictorial photography, and its price is fixed at 10 francs, or 12 francs on publication.

THE wall almanac sent out each year by Mr. S. H. Fry, the well-known trade printer and enlarger, this year bears a beautiful bit of printing in the shape of a child's portrait by Mr. Reveley, of Wantage, chic in itself, and interesting as showing the fine commercial work of Mr. Fry's staff. A copy of the calendar can no doubt be obtained on addressing a trade card to 12, South-villas, Camden-square, London, N.W. We learn, however, that Mr. Fry's business is shortly to be transferred to larger premises at Highbury, which will permit of the most expeditious handling of every class of work.

THE death is announced of Mr. W. J. Sandry, of the Triangle Photographic Studio, Paul, Cornwall. The deceased gentleman was ill for only two days.

New Material.

Sanzol. Sold by H. Edmund and Co., Ezra St., Columbia Rd., E.

Sanzol is a cobaltamine salt which has been introduced as a selective reducer—that is to say, one which reduces the density of the high-lights in preference to the shadows. The particular directions advise the solution of two grains of the salt in an ounce of water, and acidification with 14 minims of nitric acid; immersion of the negative in this solution, and rocking the dish for from five to eight minutes, and then arresting the action in an extremely dilute solution of ammonia, 14 minims to one ounce, and then a 15 minutes' wash.

Our trials on these lines have proved most satisfactory. There is a distinct selective action on the high-lights, with comparatively no action on the shadows, and it is possible to produce harmonious prints from even the hardest negatives.

We have also found that an organic acid, such as acetic, gives a much slower action, and it is therefore more under control than when nitric acid is used.

Compared with ammonium persulphate, there seems less tendency to produce flatness, but this requires a long series of comparative tests to confirm, and we hope to give later the results of our experiments in this direction. This new salt promises to be a welcome and valuable addition to our somewhat restricted list of reducers. As it has been stated that there is some frilling action with it, we are bound to say that, so far, we have not observed the slightest trace of this inconvenience. This may or may not be due to the low temperature of the solutions at the present time.

Applied to prints, such as bromide or gaslight, it is obvious that as the greatest action takes place where there is the greatest deposit of silver, the shadows are reduced more than the high lights, and therefore Sanzol will be valuable for reducing bromide and gaslight prints in which the shadows are blocked up. The reducer is issued in cartridges of three sizes—1s., 2s. 6d., and 5s.

CATALOGUES AND TRADE NOTICES.

A SET of the well-known Kohinor retouching pencil, sent to us by Messrs. Hardtmuth is a reminder which perhaps others may need as much as ourselves. Of the numerous varieties in which it is made there are seventeen degrees in the 6B—9H series, and the pencils are also put up in various styles.

ELECTION Photography in America.—A new and very practical use for the camera has come into being. We learn from an American contemporary that it has been employed in Louisville at the registration booths to photograph election repeaters. It is given credit for cutting down their number, for when the repeaters saw the camera turned on them they began to have business elsewhere.

SEIZURE of Obscene Photographs.—Probably the largest plant in the United States for the production of obscene photographs has been discovered in Chicago, and its business has been broken up by the police. Secret service officers of the Post Office Department have for several years been seeking the place where thousands of obscene pictures came from, and recently, with the assistance of the police, they found it at 173, Milwaukee Avenue, Chicago. The alleged proprietor, Thomas Collins, was arrested and sent to jail in default of 3,000 dols. bail, while 120,000 obscene negatives were seized.

The new Under Secretary for the Home Department, Mr. Herbert Samuel, is probably the only member of Parliament who ever contributed to the illustration of a Government publication. When Mr. Samuel was in Central Africa he took a number of excellent photographs, which were afterwards embodied in a Foreign Office Blue-book.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held December 19, Mr. H. Snowden Ward in the chair. Mr. Max Ferrars gave a lantern lecture on "Photography as a Means of Picture-making," in which he set forth at considerable length the limitations of photography. One chief defect of the photographic process was its incapacity of simultaneity, a defect which removed many subjects from its scope. Mr. Ferrars made the very strongest claims on behalf of straightforward photography. The numerous expedients to be classed as "fake" or "control" were described by him as often failing in the very purpose they set out to achieve. As an example, he showed a photograph of a lake, with "breadth" imparted to the distant mountain range by artifices of lighting alone. A comparison print, in which greater "breadth" was given to the mountains by the use of a coarse paper, was less effective, as the delicacy of the foreground, which in the first print heightened the masses of the distance, was altogether destroyed. The whole tenour of the discourse was to decry "fake" as a species of fraud equivalent, as one speaker remarked, to putting marks of the file or hammer on cast iron to create the impression that it was a piece of wrought metal. The congruous character of a photograph was lost in almost every instance where control was resorted to. Mr. Ferrars exhibited a number of slides, in which he had sought to carry out the principles inculcated in the lecture.

THE rooms of the Royal Photographic Society will be closed on Saturday to Tuesday inclusive during the Christmas holidays.

SOUTHAMPTON CAMERA CLUB.—On Monday evening, the 18th inst., at the Philharmonic Hall, Mr. A. E. Henley lectured to the members on "St. David's Cathedral." He dealt historically and by means of very excellent slides with this mediæval Mecca of the Pilgrims, pointing out how in olden days two journeys to St. David's were accounted equal to one to Rome. The architectural beauties of the building were fully depicted—miserere, capital, canopy, and stall carving being illustrated, both by slide and legend in their turn. Mr. Henley also illustrated the outdoor beauty spots of the immediate district.

SOUTHPORT PHOTOGRAPHIC SOCIETY.—Mr. J. T. Rigby having resigned his position as hon. secretary to this Society, the Council has elected Mr. A. E. Sharples, of King's Chambers, 8, Tulketh Street, as hon. secretary, with Mr. C. Woodall, of Portland Street, as hon. assistant secretary.

PHOTO ART CLUB, ABERDEEN.—A lecture entitled "Foundations of Modern Architecture" was delivered by Mr. David, of Gray's School of Art, last week. The lecturer had a number of excellent slides, and his plan of lecture was to put on the screen examples of ancient architecture, followed by views of local buildings, in

which the ancient ideas had been carried out. He showed views of such places as the Egyptian Hall of Columns, Greek Parthenon and Erectheum, the Church of St. Peter's in Rome, and the Italian Riccardi Library of Florence, with their modern British prototypes. Mr. David's plan of lecture made the subject specially interesting and easily understood.

PLYMOUTH PHOTOGRAPHIC SOCIETY.—At the closing meeting of the winter session on Friday, December 15, the President, Mr. T. J. Johnson in the chair, a very happy arrangement was made, the evening being devoted to three holiday trips by three members, illustrated, of course, with lantern slides. The first was "The Rhone Glacier and Valley" by Mr. H. S. Hill, who, while disclaiming the idea of a lecture, was able to describe the district which his slides illustrated. They were an exceedingly fine lot, dealing with the marked contrasts of Alpine scenery in a very capable way. Mr. Hill explained that they were all hand-camera shots, the instrument used being one of the earliest of Beck's "Frenas," which he had used continually from its first issue in 1892 or 1893. It was still capable of doing good work, as was evident. Mr. W. Grist showed some splendid landscapes in the vicinity of and near the banks of the Tamar. Following these came a series of views illustrating a tour among the English lakes, characterised by good technique and a wonderfully fine average of striking skies. These were the work of Mr. F. Johnson. His views of Furness Abbey were exceedingly fine. The evening proved to be one of the most enjoyable of an excellent series.

RICHMOND CAMERA CLUB.—On Thursday evening in last week a large collection of exceedingly fine lantern slides from photographs of flowers was shown by Dr. Rodman. The negatives were made upon colour-corrected plates, with a yellow screen, and as a result the light values were well represented. The pictures comprised orchids, narcissi, roses, pansies, fruit blossoms, lilies, chrysanthemums, and other flowers in a great variety of colours. Dr. Rodman stated that the majority of the negatives were taken in a room with a north light. A self-coloured background was best, as, if it is of suitable colour and placed at a good distance from the plant, it affords nothing to attract the eye from the main object. It was necessary to work with a large aperture, to obtain as short an exposure as possible, on account of the natural tendency of flowers to droop and to turn to the light. In many of the pictures shown an exposure of two minutes had been given with a Zeiss lens working at $f/8$. The great advantage to be obtained by using orthochromatic plates in combination with a yellow screen was very clearly proved, as it would have been impossible to produce equal effects with any ordinary plate.

ULSTER AMATEUR PHOTOGRAPHIC SOCIETY.—Meeting held December 12. The president, Mr. D. Elliott, in the chair. The programme for the evening included "Photographic Queries and Replies," by members, as well as a short lecturette by the president on "Stereoscopic Photography." Among the questions asked and answered were the following:—A beginner wants to know what the terms anastigmat, aplanat, and symmetrical mean used in reference to photographic lenses? Answer—An anastigmat is a lens which, as well as being corrected for spherical and chromatic aberration, is corrected for astigmatism. An aplanat is a lens corrected for spherical and chromatic aberration, but not for astigmatism. A symmetrical is a double combination lens, where the front and back halves are of equal force. Another beginner wanted to know why gaslight papers stain brown so readily. Answer—Gaslight papers are generally developed with metol, a substance which oxidises very freely. A print exposed to air for a minute or two after development and before fixing will discolour, because the metol absorbs oxygen, and hence stains the paper. Yellow high-lights are caused

by (1) too weak or exhausted developer, (2) under-exposure, or (3) too long development. Notice was given by the honorary secretary (Mr. Thomas N. Murray) that the Armagh Show for 1906 would be held on the 27th and 28th of June, and the Newry show on the 3rd and 4th of July, both of these agricultural societies having a photographic section. The Lord Mayor's (Right Hon. Sir Daniel Dixon, Bart., M.P.) 1905 gold medal was won by Mr. W. D. Elliott. T. Bryans was a good second. Prints were judged by Mr. Charles F. Inston, of Liverpool. The entries were much better all round than last year, showing thought and care, and each competitor got his print returned with critique.

Commercial & Legal Intelligence

A MOUNT Dispute.—Arthur Wm. Holmes, photo-mount maker, trading as "The Leicester Showcard Works," sued H. B. Cooper, photographer, Abbey Park Road, for £1 17s. 6d. for goods sold and delivered. Mr. Flavell (Messrs. Harding and Barnett) appeared for plaintiff. The dispute in this case was as to the printing of the photographer's name and address on 250 large-size photograph mounts, the defendant contending that he gave an order for the mounts to be the same as previously supplied, and when they arrived he found that there was not room on the mounts between the name and the address for printing in the titles of the groups for which the mounts were intended. Plaintiff admitted that it was understood the mounts were to be as similarly supplied, but said no sample was given him to go by, and nothing was said to him about leaving sufficient room for the title. His Honour gave judgment for the defendant.

BARRAUDS, LTD. (Photographers, Liverpool).—Issue on November 15 of a debenture for £300, part of a series created same date, to secure £500, charged on the company's property, present and future, including uncalled capital. No trustees.

BERNARD COOPER, LTD., Photographers, London.—A debenture, dated December 2, 1905, to secure £50, charged on the company's undertaking and property, present and future, except uncalled capital, has been registered. Holder—Mrs. M. M. Hadfield, 28, Victoria Mansions, Willesden Green.

UNIVERSAL OVERLAY SYNDICATE, LTD.—Registered, December 4. To carry on the business, among others, of photographic printers, engravers, etc. No initial public issue. Registered office, Trevelyan Buildings, Corporation Street, Manchester.

ENGRAVED ROLLER SYNDICATE, LTD.—Registered December 1, by Jordan and Sons, Ltd., 120, Chancery Lane, W.C. Capital, £250 in £1 shares. Object, to take over a process discovered by J. Ackerly and the business of a photographic engraver, as applied to the surface of rollers and other cylindrical bodies now carried on by him at Manchester, and to carry on the business, and that of photographers, designers, etc. No initial public issue. Registered without articles of association. Registered office: 54, Arcade Chambers, St. Mary's Gate, Manchester.

FAILURE of a Burton Photographer.—At the Burton Bankruptcy Court last week, before Mr. Registrar Hubbersty, George Renwick appeared for his adjourned examination, the liabilities being £99 2s. and the assets £19 7s. 7d. The bankrupt said he commenced business in 1875 as a photographer, having £20 capital. He did not realise that he was insolvent until the present year, and attributed his failure to keen competition, bad trade, and illness. For some time his gross income had been £3 or £4 per week, and he lived at the rate of £1, the remainder going in expenses and business losses. The examination was closed.

An Order for Photographs.—Messrs. Duyshart and Co., photographers, of Chelmsford, sued Mr. F. W. Rogers, head master of Chelmsford Grammar School, for 30s. for photographs supplied. Mr. Jackson, for the plaintiff, said that an under-master at the Grammar school called with Mr. Moosajee, a pupil, dressed in the uniform of the School Cadet Corps, at the plaintiffs' studio, and said a photograph of Mr. Moosajee in uniform was required for the school magazine, and that some photographs in private clothes would also be wanted. Mr. Moosajee was photographed, and the photograph duly appeared in the school magazine. Plaintiffs executed twelve photographs, and sent them to the school, but they were returned by Mr. Rogers, who wrote: "Mr. Moosajee did not order them, neither did I. We wanted his photograph for the magazine, and he intended to have some more. If you can show a written order, of course it must be settled." Mr. P. J. Duyshart, in his evidence, said he wrote to Mr. Moosajee and sent him the bill, asking him to get a cheque from Mr. Rogers. His Honour: Why didn't you send direct to Mr. Rogers? Witness: I was informed that the order was from a boy, covered by Mr. Rogers. Mr. Suthery, for the defendant, said that Mr. Rogers never gave any order for the photographs. His Honour said there was no evidence of Mr. Rogers giving an order except for the negative for the magazine. Mr. Suthery: Mr. Rogers is willing to pay the 7s. 6d. for that at once, and Mr. Moosajee will also pay for the six photographs he ordered. His Honour gave judgment for the plaintiffs for 7s. 6d. and 3s. court costs.

LIBELLING A Photographer's Wife.—A singular story was told at the Leeds Assizes on Monday last before Mr. Justice Darling, when Mrs. E. Sagar, wife of a photographer residing at Shipley, brought an action against the Keighley Herald Printing and Publishing Company, Limited, with whom were associated the editor and publisher of the paper, for libel. It was alleged by the plaintiff that on August 12 an article appeared in defendant's paper, headed "Keighley Elopement Frustrated," "Scene at Ingrow Station," in which an amusing account was given of a scene at the railway station. Reference was made to Mrs. Sagar's search for her husband, who was said to have eloped. She was described as the wife of a local artist, a brunette in blue, and a female detective who had been in search of her recalcitrant husband. Counsel submitted that there had been no elopement, and that the story unduly reflected on the plaintiff. The article began as follows:—"Ingrow Railway Station has just been the scene of one of the many melodramatic incidents which go to make up the life-stories of certain of our fellow beings. Seated in the waiting-room, pending the arrival of the 5.46 p.m. train, were an apparently devoted couple. The lady was fair to look upon, and wore a becoming costume of pale blue. The gentleman, though not particularly handsome, devoted much attention to the twirling of his fair and flowing moustache. What the root of this curbed emotion was was presently manifest, for a few minutes before the arrival of the 5.46 train a dashing young brunette, smartly attired in a semi-sailor blue costume and large picture hat, appeared on the platform. After casting round a few angry and questioning glances, she evidently spied the loving couple in the waiting-room, whom she bore down upon like an eagle." The Judge: An eagle in a picture hat and a sailor costume? (Laughter.) Other quotations from the vivid writers on the "Keighley Herald" followed, and the jury gave a verdict for plaintiff for £75.

At the recent exhibition of the Hove Camera Club the committee purchased for the club's permanent collection "Shoeing," by Mr. Harold W. Lane.

The latest list of the Charles Urban Trading Company, 48, Rupert-street, London, W., is a 36-page pamphlet, descriptive of this firm's well-known educational films for the bioscope.

News and Notes.

EDITORIAL Changes.—With the New Year the editorship of our contemporary, the "Photographic News," passes into the hands of Mr. F. J. Mortimer, F.R.P.S., who thus severs the connection with the "British Journal of Photography" established on his joining its staff in 1904. Mr. P. R. Salmon, F.R.P.S., the retiring editor, is identifying himself, we are informed, with the editorial control of the "Photographic Dealer," and both gentlemen, we are sure, will have the hearty good wishes of a host of friends.

The marriage of Mr. F. J. Mortimer, F.R.P.S., to Miss Lavinia Romer took place at the Church of Holy Trinity, Clapham, S.W., on Tuesday last, December 19. The bride and bridegroom left town the same afternoon for a short holiday in the Scillies.

"ACETYLENE," the organ of lighting with acetylene gas, reproduces in its December issue a couple of photographs of banquet rooms lighted by acetylene installations.

DAYLIGHT Loading.—A writer in the "American Inventor" can surely have not kept himself *au courant* with British manufactures, or he would not raise the cry for a piece of apparatus such as that which he describes as follows.—"What is needed in inventions of this character is an improved form of plate holder which will carry a greater number of plates, or else be so arranged that additional plates may be inserted in the holder while in the camera and without exposure to the light. There would be considerable value to a plate holder which would allow of a number of plates being carried and changed without removing any plate from the camera. There is no question as to the commercial possibility of this invention, provided the construction designed is thoroughly and entirely practical."

The fifth annual dinner of the employees of the Rotary Photographic Works at West Drayton was held at the Swan Hotel last week.

Our recent notice of the "Kokka," a kind of Japanese "Studio" in magazines devoted to the fine arts, has apparently brought to our table a copy of the "Nippon Bijutsu," also a monthly magazine of the fine arts, published at Miyana-ga-cho, Nezu, Tokio, price 3 yen, 40 sen a year, post free throughout the world. The "Nippon Bijutsu" aims to reproduce contemporary art, and the number before us contains a few pages devoted to this purpose, but the major portion is literary matter, any criticism of which we have our own reasons for withholding.

ACTION of Wood on a Photographic Plate.—Dr. W. J. Russell writes to "Nature" of last week:—"I have recently seen some photographic plates used at the last eclipse which have on them not only pictures of the sun, but also pictures of the wood forming the dark-slides in which they had been placed. At a former eclipse I understand a similar disaster occurred. It may, therefore, be well for me again to state that wood in contact with, or in near proximity to, a photographic plate, even in the dark, can impress upon the plate a clear picture of itself. This action is much stimulated by high temperature and brilliant sunshine. It can, however, be stopped in several ways. Probably the simplest one would be to make the slides of copper in place of wood."

WARWICKSHIRE Photographic Survey.—A selection of the photographs taken by the members of this society during the past season is now on exhibition in the Birmingham Art Gallery, amongst the contributors being Sir Benjamin Stone, M.P. The collection includes a number of Birmingham street scenes, views in Warley Woods,

meets, sports, plough trials, churches, and old buildings at Stratford, Henley, Berkswell, Lapworth, Compton Wynates, and many other Warwickshire villages, and a series taken at Solihull in 1853 on old paper negatives.

OTHERS—and Ourselves.—Unconscious humour in the "Daily Mirror" of Friday last, wherein we read at the head of some reproductions of Dr. Schilling's flashlight photographs of wild beasts:—"These flashlight photographs are taken during a flash lasting a fiftieth part of a second, caused in exploding magnesium powder by gun-cotton. The 'Daily Mirror' has a large flashlight staff." It appears to be by the merest chance that our contemporary's staff has not photographed lions and leopards on the Thames Embankment.

LEEDS Technical Schools Photographic Section.—On Saturday, December 9, the students of the above classes held their annual reunion and dinner at the Griffin Hotel, Leeds. Thirty-five students, past and present, attended. The chair was taken by Mr. J. Ingham Learoyd, Halifax, supported by Mr. H. Snowden Ward, F.R.P.S., London, and Mr. S. E. Bottomley, F.R.P.S., lecturer to the classes. Mr. H. Snowden Ward gave the toast of the "Classes in Photography at the Leeds Technical Schools." Mr. S. E. Bottomley, replying on behalf of the students, thanked Mr. Ward for his excellent address and for the words of encouragement he had given the students.

THE Whitechapel Exhibition.—In reference to the exhibition of photographs now being held at the Whitechapel Art Gallery, we have received the following letter from Canon Barnett, chairman of the committee, asking for contributions towards the expenses of the enterprise. We publish the letter, but we cannot see that the organisers of the exhibition can expect support from the photographic community. A committee which sets itself the task of introducing photographic art to the East-end should surely count the cost beforehand and be prepared to discharge its financial obligations. Canon Barnett writes:—"The Photographic Exhibition in this gallery is now drawing many thousands of visitors. The trustees are encouraged to believe that the interest awakened may make many East Londoners take up photography as an occupation for their leisure. They know that your readers will welcome such an extension of interest, both for the sake of the art and for the raising of popular taste. The cost of the exhibition is necessarily greater than can be met by the offerings of East London visitors. The trustees desire to ask your readers if they will help by sending a contribution to the treasurer at the gallery."

THE American Photographic Copyright League is just at present undertaking a tremendous work in the interest of all photographers. A new copyright law is before the coming congress, and the League has undertaken to see that photographers get their just rights, which seem in danger of being overlooked and left, if possible, in a worse position than before. As pointed out by "The Photographer," the law as it now stands prescribes certain rules which are being broken daily by men who have applied for and obtained protection for their products. Time and again the courts have ruled that a copyrighted picture must be labelled according to the formula laid down, and that any deviation, however slight, invalidates the protection. Yet every day we find in books, magazines, newspapers, and on original photographs sent out by the photographers themselves an incorrect labelling and a consequent loss of all protection in case of wilful reproduction. The photographers are to blame if the newspapers and magazines care nothing for the rights of the author of the pictures they use or if they invalidate the protection by incorrectly labelling them, and it is to teach the photographer his rights and how to protect them, and also to see that redress is obtained when his rights are violated, that the league was founded.

Correspondence.

* * *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

* * *We do not undertake responsibility for the opinions expressed by our correspondents.*

THE INVENTOR OF THE ENAMEL PROCESS.

To the Editors.

Gentlemen,—In your issue of October 27 there is a letter by Mr. Gamble on "Process Work in America," and I wish to refer to one sentence, in which he says "The man (an Englishman) who discovered the enamel process admitted that he got the idea from an old "British Journal Almanac."

Apparently the name of the inventor of the enamel process is unknown because about once a year I see references to both this and the fish-glue process on your pages generally accompanied by an expression of surprise that the inventors' names are unknown. I am of opinion that some effort should be made to find their name so that due honour may be paid to them, as in all likelihood this is the only reward they will ever receive, and I enclose a communication which may help towards this desirable end.

About the time of the World's Fair in Chicago I made the acquaintance of Wm. H. Hyslop, a brother Scotsman, who was at that time keenly interested in ordinary process and three-colour work. He claimed to be the inventor of the popular fish-glue process, and his claim I have never yet seen denied. About twenty years ago, I think, Mr. Hyslop was well known in your city among advanced workers, because I have noticed in the "Almanacs" of that period that he is advertised by Dallmeyer as being one of the users of his lenses.

For many years Mr. Hyslop has been the victim of a very incurable disease which has made him a physical wreck, and his end cannot be far off, so I wrote to him on the subject, believing that he could give some authoritative information, and his reply I enclose, hoping that it may help in the solution of the enamel process mystery.—Yours truly,

F. DUNDAS TODD.

The Photo-Beacon, 808, Security Building, Chicago.

December 4, 1905.

The following is the letter referred to by our correspondent. It is addressed to him by Mr. Wm. Henry Hyslop:—

"Your letter finds me in great pain, but as it has lasted five weeks, and may last to the end, I will try to answer your letter as shortly and plainly as possible.

"I am not the originator of the enamel process, but I understand it was an Englishman working in Philadelphia that was so. I forget his name. The original process is simply a modification of the dusting-on process, and it is quite likely he got most of his details from the BRITISH JOURNAL OF PHOTOGRAPHY, but there are some things in it which certainly must be credited to him, as I am quite certain they never appeared in the BRITISH JOURNAL OF PHOTOGRAPHY or anywhere else.

"Many years ago I was in Philadelphia, and the process was given to me *minus* the necessary details, and when I got back and found it would not work I immediately set about finding a medium which would work, and this I found in fish glue. Now, it is very probable that as far as the fish glue enamel process is concerned, I am the originator. One thing I know to a certainty, is that I am the first person who gave the process to the public, and who wrote a practical article giving full directions. This

article was published in a Chicago paper, "The Printer Journalist," a man of the name of White being the then editor. It was at that time published on Adams Street, but it is either dead or gone somewhere else.

"My name should have been printed to that article, but by some mistake it was overlooked, and although it was published and republished in all quarters of the globe, I got no credit therefrom. There have been many aspirants to the honour, but the foregoing are the facts.

"Some six years ago I was told that the details of the original process had been practically public property, and that it was ousting the fish-glue process, but this I can quite understand, as in many ways it is surer and better. However, the fish-glue process can be used in exactly the same way, and I am not sure that used in that way it is not best of them all.

"If you don't hear from me again, I wish you good-bye and good luck."

STREAKS ON GASLIGHT PAPERS.

To the Editors.

Gentlemen,—Referring to your article on "Gaslight Papers" in last issue of "The Journal," I may be allowed to point out that the writer is a little behind in the treatment of streaks or pencil-like scratches. A better way to get rid of these is to prevent them appearing at all, and that can easily be done by adding a few drops of methylated spirits to a metol-hydroquinone developer. (I have not tried it in any other developer.) This may be new to your readers, as it only occurred to me a week or two ago to try it, and I found it successful. I use four to six drops per ounce of developer.—Yours truly,

NORMAN HUNTER.

The Studio, Port-Glasgow, December 18, 1905.

COPYRIGHT AND ELECTION PHOTOGRAPHY.

To the Editors.

Gentlemen,—I have read your interesting "Almanac" from the first with ever-increasing interest and profit, but this year I consider you have placed the whole of the profession under a deep obligation by the very lucid and clear article on the laws of copyright. You have managed to place technical terms in such simple language that all can understand, and one would have thought it embraced the whole subject. Yet there is one point on which I feel uncertain, and shall be glad if you will kindly enlighten me. The question is, Is it necessary to register each position taken of a sitter to ensure the copyright? For instance, I have just taken both candidates for the new Parliament, and have taken vignettes and $\frac{3}{4}$ figure, the vignettes being exactly like the $\frac{3}{4}$, only taken nearer, and, of course, head only. Must I register both? Again, I take the negatives in duplicate, hoping to have a run on them, and on developing them find my sitter, while I was shifting the plate of the $\frac{3}{4}$, has extended the finger of the right hand, which in the first exposure was closed, and in the case of the other sitter, while I was shifting plate, he has pulled down white cuffs, which do not appear in the first.

I am glad to note that copies ordered by the sitter after receiving a few complimentary copies does not interfere with the copyright.

In conclusion, may I add that the form of licence for use of photographs on p. 664 will doubtless be of much service to many besides.—Yours truly,

J. P. S.

December 18, 1905.

[As the Copyright Act very clearly correlates "a photograph and the negative thereof," it is inadmissible for the registration of one print to serve for several negatives, even though the differences are so slight, as in our correspondent's case. The fact that such differences exist would be sufficient, in an action, to prove that one

or other of the particular photographs had not been registered, and that, therefore, the proprietor of the copyright could make no claims in respect of infringement of the unregistered prints.—Eds. B.J.P.]

SOME HOLIDAY PROBLEMS.

To the Editors.

Gentlemen,—I see your last issue reports a meeting at which the question one speaker raised was that of an examination for the "general assistant." I entirely agree that such an examination should be conducted, in no narrow spirit, and as the holiday season may perhaps afford an opportunity for some of your readers to consider any suggestion at leisure, and with the mind mellowed by Christmas cheer, I may perhaps put down one or two questions from which some indication of the kind of examination desirable may be—or may not be—found. Probably not.

State what you know of: (1) Sandow's views on stand development; (2) The use of magazine changers in lending libraries; (3) The nutritive value of Velox.

Distinguish between a "free sitting" and a "free portrait swindle." Fractions may be used.

Discuss the law of C. Olney Hatch, that "the copyright value of a photograph decreases with the focal length of the lens." Show that as the focus becomes shorter the product is a perfect "sphere."

Assuming the capacity of a hansom cab to be one perfectly groomed man, calculate the traffic area in Pall Mall East. Express the result in long acres.

What is whisky? Give any reasons you may have against its use for the rapid drying of negatives.

A goldfish in the ponds of Sans Souci is reported to have used the word "photography" every 9th of May for the past hundred years. Discuss the probability of the truth of this assertion in reference to recent research.—I am, Sirs, yours very truly,

YORICK.

[We must ask our correspondents not to attempt competition with "Yorick," whose communication is admitted in appropriateness to the season.—Eds. B.J.P.]

ENTRIES for the third Scottish salon will close with Mr. V. C. Baird, Broughty Ferry, N.B., on Saturday, December 30.

MR. WM. A. FRAME informs us that, owing to his departure abroad, he has resigned the post of the secretary of the Glasgow Southern Photographic Association, and that the secretary now is Mr. Charles Young, 217, Crow Road, Partick, Glasgow, to whom all future communications should be addressed.

FORTHCOMING Public Exhibition at Derby.—Dr. Collier Green, the president of the Derby Society, made the interesting announcement at the fourth indoor meeting of the winter session that arrangements had been made for the holding of a photographic exhibition in the Art Gallery under the auspices of the corporation early in February. The corporation had been approached in the matter, and had readily acquiesced, and a sub-committee of the society had the matter actively in hand. There would be open classes and local classes, and medals would be offered by the corporation, whose only condition was that the work of the members of the Derby Photographic Society should be adequately represented.

M. LEON VIDAL, who for many years has conducted our French contemporary, "Le Moniteur de la Photographie," is withdrawing himself from these duties, which, he tells us, encroach too much upon his many other interests. M. Vidal will be succeeded by M. Charles Gravier, but he will not thereby dissociate himself altogether from photographic journalism. It is his intention to bring out an annual review of the industrial applications of photography—a task in which he has our most cordial good wishes.

Answers to Correspondents.

- *• All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- *• Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- *• Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- *• For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 1d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPH REGISTERED:—

Annie Bourke, 213, South Street, Perth, Scotland. Photograph of the New Altar St. John's R.C. Church, Perth.

FERRICYANIDE INTENSIFIER.—

Having read in some "Photographic Notes" that potassium ferricyanide might be used in place of bichloride of mercury for the purpose of intensification, I bleached a negative in a solution of ferricyanide, to which, however, I found it necessary to add a little hyposulphite of soda before it would act. The negative was then thoroughly washed, and I applied to it a pyro-soda developer to bring back the image, but with no result; the plate remained perfectly clear glass. Will you kindly tell me if the negative can in any way be restored?—E. H. ALLEN.

It cannot. The image has been removed by the Farmer's reducer which you have prepared. You must use a plain solution of ferricyanide, or with a little ammonia if it works too slowly.

INVISIBLE INK.—I think you recently gave an article in the JOURNAL on "Invisible Writing," but although I have looked through two or three numbers, have not been able to find it. I should be greatly obliged if you could give me a formula, or number in which it was published, for invisible writing to be produced by an after process, or heat for preference.—W. W. HAZELBY, Jun.

You will find the formula on p. 987 of the "Almanac." It is: Chloride of cobalt 25 grs., distilled water 1 oz. (fl.) Writing executed with this ink is first pink on paper, becoming invisible on drying. On warming, the writing turns blue.

COPYRIGHT.—I should be glad to have your advice on a copyright question. A photograph appeared in a local paper last Friday which I took, and I have now copyrighted same to-day, December 18. As I have published a postcard of the print which the paper has used without consulting me, it has probably done harm to my reproduction. I may say it was a public affair, and I presented copies to the parties interested and was not paid for doing it. Haven't I a clear case against them from December 18? As it is a weekly paper the sale will probably go on for some days after this date. What is the most advisable thing to do to recover anything from the newspaper people?—PRESSMAN.

You can stop the sale of further copies and obtain penalties for publication after registration. But we should advise you to write a fair letter to the paper, asking them to make you an offer. (See par. 22 in the "Almanac" article on "Copyright.") If you are a member of the Professional Photographers' Association you should put the matter in their hands.

VECTIS.—A bald statement that A. and G. Foucault had prepared a print-out bromide paper appeared in the "Bull. Soc. Franç." 1905, p. 107; a further statement was made, and specimens shown, loc. cit., 1904, p. 255. Both were noted in our columns at the time, but this is all that has appeared.

Absolutely no information is given as to the method of preparation, beyond the statement that "an entirely new modification of silver bromide had been discovered." We might add that we have very carefully watched for any further information, and that in the above statement you have the gist of all that has appeared, and that it is a mere waste of time to turn up the above references if you hope to learn anything.

HYPHO-ELIMINATOR, ETC.—(1) On p. 791 of the "Almanac," ammonium persulphate is regarded as the best hypo eliminator; on p. 955 is a formula. I know this substance as a good reducer, and should be glad to know if there are any working instructions. (2) I have difficulty in firing flash powder with a white-hot platinum wire. Could you help me?—Q. S.

(1) Better follow the instructions given with the commercial persulphate eliminator issued as "anthion," and obtainable from your dealer. (2) Try spreading the flash powder on a little guncotton.

A DEVELOPING FORMULA.—Would you be so kind as to print a formula suitable for developing midget negatives, taken with incandescent gas light? I have looked in the "Almanac," but do not see any specially recommended for this purpose. Would I be right, in mixing up developer, to use the grain weights as used with apothecaries' scales?—SUBSCRIBER.

Imogen sulphite is a good developer for the purpose. A. Imogen sulphite 1 gr., water 12 oz. B. Sodium carbonate 1 oz., water 2 oz. Use 1 oz. of A, 3 oz. of B, and 4 oz. of water.

STUDIO LIGHT.—I have just had a Westminster Engineering Co.'s arc lamp fitted in studio (which is commodious). Arc light is movable, and there is also room for moving backgrounds. But I cannot get results in portraiture owing to shadow of sitter reflecting on background. Tissue screen doesn't alter it. Can you help me with suggestion, or name of book on subject, if any?—NOVICE.

We can only suggest that the sitter is too near to the background, and that the lamp is too low. Try alterations in these two respects, and write us again if you fail. There is no book of any account on artificial light portraiture.

P. HENDERSON.—Hetley and Sons, Soho Square, London, W.

GEO. WOOD.—Henry Lindenmeyr and Sons, Upper Thames Street London, E.C.

GERALD CARTER.—Probably the postcard publishers would select a number. Your friend might offer them in a small advertisement in our columns.

F. P.—Theoretically there is scarcely any advantage in using the smaller stop, but with almost any lens you will obtain better definition at $f/45$, and with any of the cheaper lenses a notable improvement.

*• NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

The Bleaching Out Process of Colour Photography. Professor Kümmell, in the current number of the "Photographische Rundschau," comments upon this process of colour photography as described by

Neuhauss, and suggests the following modifications, which are based on his own experiments:—The first experiments certainly gave reproductions of the colours, but there was always a very distinct red fog, which is ascribed by Professor Kümmell to the poor sensitiveness of the erythrosine used. In justice to Dr. Neuhauss we ought to point out that it was he who laid great stress upon the very accurate adjustment of the ratio of the quantity of erythrosine, and that the slightest excess of this dye causes the red fog of which the author speaks. Satisfied, however, that the fault was in the dye, Professor Kümmell has tried three different erythrosines, namely, tetrachlorotetra bromofluoresceine, tetraiodofluoresceine, and diiodofluoresceine in the form of the sodium salts. These dyes were obtained commercially, and also home prepared, each mixed with gelatine solution, coated on paper, sensitised with hydrogen peroxide, and exposed under a photometer. The tetrachlorobromo-fluoresceine proved to be the least sensitive, the most sensitive, the diiodofluoresceine, and midway the tetraiodofluoresceine. The last appears to be the dye used by Neuhauss, as its bluish-red colour seems the best fitted to give black with auramine and methylene blue, whilst the most sensitive diiodofluoresceine shows an orange tinge. The sensitiveness of the red dye can be increased by using the ammonium instead of the sodium salt. It has been noted that very pure dyes are less sensitive than those which contain small quantities of impurities especially traces of iodine. Tetraiodofluoresceine mixed in gelatine with auramine and methylene blue gives red fog, whilst with diiodofluoresceine the red parts of the picture

bleach out. Professor Kümmell has therefore tried to use both dyes simultaneously, and has replaced one fourth of the tetraiodofluoresceine with diiodofluoresceine.

Catalytic Aids to Sensitiveness.

Catalytic agents, as Neuhauss states, produce in many cases increase of the sensitiveness. Iodine appears to act with erythrosine, as already mentioned, as a catalytic agent. The strong catalytic action of colloidal solutions of the noble metals with hydrogen peroxide is well known, and it has been tried whether they would have the same action in the gelatine and dye mixtures; the gelatine was mixed not with pure water, but with colloidal solution of gold; the mixture was used in the same way as the others. The sensitiveness was in many cases considerably increased; the experiments are not yet concluded, but this action was distinctly noted when the gelatine was a little damp. The coloured gelatine can be transferred to paper as follows: Plate glass should be well cleaned, then rubbed with a solution of wax and resin in benzole, and polished. The gelatine mixture is then coated on this. After drying the gelatine should be superficially damped with a wet brush, then a damp sheet of paper squeezed into contact and the whole dried. As soon as thoroughly dry the paper and gelatine will spring away from the glass.

Getting Business.

Some little time ago we referred to the use of the price list in a very simplified form as a circular. It is possible to distribute a large number of such circulars without any great amount of business resulting from the effort, and we should be inclined to say that spasmodic efforts in advertising are as futile in this as they are in any other direction. The world is increasingly made up of business-like people, men, and women too, who are generally as much in touch with the restless and relentless activities of commercial life as the average photographer. They are exceedingly quick to see when a man is in earnest about his business, when he is adopting keen, alert, business-like methods, and we believe that just as we are a nation of shop-keepers rather than a nation with artistic perception so will the buying public prefer to go where business methods are adopted. Instead then of sending one circular and then another twelve months later, why should not the first circular be sent, and in perhaps a month a second communication, type-written, on a duplicating machine for preference, calling attention to the previous circular. The objection may be raised that the cost of postage is heavy. This is so, but largely because a great number of circulars are posted to people who are quite unlikely to become profitable clients. A good deal more time should be spent in preparing a list of probable customers, and then

these should be gently reminded of your active presence in their midst at frequent intervals. We would lay it down as a rule that the same circular should never be posted twice, something different in size, style, and matter being much more likely to be perused.

The Right to One's Face.

There appears to have been a little unpleasantness, last week, at a Baker Street bazaar. Miss Marie Corelli, on entering the building, was photographed, and the portrait has been reproduced in the illustrated press. It is now clear to a writer in the press (who refers to "our bazaar") that this is a species of gross libel upon defenceless women. The particular instance, which is so shocking, appears to be the representation of Miss Corelli attaining the "kindly object" of benefitting a fund established for charitable purposes. The public, we are sure, will protest against this denial of their right to see, in print, the earth's greatest and best going about on their errands of benevolence. If this be libel, it might be left to even greater philanthropists than Miss Corelli to object. However much one may approve, the suppression of the portrait, in this instance, the right of the photographer to photograph any object in which there is no copyright must remain unchallenged, and we may be sure that if any act of his institutes a libel the law will not withhold its remedy from the victim.

* * *

Photo-Buttons.

The announcement of the General Election has confirmed our suggestions of a week or two ago, that photographers would find the occasion one for business in the portrait brooches sold under the designation of "photo-buttons." A very popular variety of button is made with a mirror back, a form which it is suggested is most saleable among the feminine sex. As the smaller buttons of this, or any other, description are those which sell most readily, it may be well to point out that the mirror back should not be of flat glass, but should have a slightly convex surface, with the desirable object of exhibiting more of the possessor's face—albeit on a reduced scale—when he or she employs it for this purpose. The better class of buttons are put up with mirrors of this description, and the point is one worth bearing in mind when purchasing.

Medals—At a Price.

We were surprised the other day by the receipt of an official-looking document emanating from the "Exposition Internationale des Arts et Métiers," of Brussels, informing us that a gold medal had been awarded to the THE BRITISH JOURNAL OF PHOTOGRAPHY. Our surprise sprang from the fact that we had never heard of this particular body, and had taken no steps towards obtaining its award. The unsolicited tribute, however, of the "Exposition" is not entirely ingenuous. The document proceeds to inform us that a certificate of the award will be forwarded on receipt of five francs; that the medal itself will cost twenty francs, or may be had in bronze or silver at correspondingly lower prices, which are plainly printed in the tariff on page 2 of the circular. Our contemporary, "Truth," in commenting on the circular, invites any information as to the alleged "Exposition des Arts et Métiers," and associates it with a Parisian named Boettcher, and other parties, English and foreign, who have been prepared to grant diplomas to anybody who would pay for them.

TESTING THE STABILITY OF SILVER PRINTS.

It is an undeniable fact that more photographs, which will prove fugitive in the near future, are being produced at the present time than was ever the case before. That an amateur's pictures may fade is of very little moment to anyone but himself. He does not sell his work, he merely keeps it or gives it away to friends. With the professional, however, the case is quite different. His customers pay for their pictures, and therefore have a right to expect that they should not deteriorate within a few years of their being supplied to them. It is not at all unusual to hear the remark, when fading pictures are seen, that "all photographs fade you know." The reproach to photography is one that it does not of necessity deserve. There are silver prints by the thousand in existence that were made fifty or sixty years ago which are still as good, to all intents and purposes, as they were when first produced. These pictures stand as a proof that the phenomenon of fading is not inherent in silver pictures.

If such photographs were produced so long ago, and at a time when a knowledge of the chemistry of the subject was so scant, one may well ask why do many of the modern prints pass into the sere and yellow leaf so quickly? One thing is certainly noteworthy, namely, that the past generation of photographers were evidently more concerned about the stability of their productions than seems to be the case with their successors. Some fifty years ago the Photographic Society of London, now the Royal Photographic Society, appointed a committee of experts to inquire into the subject of fading photographs, and a report on the subject was presented. Since that time very little has been done with regard to authoritative investigation of the best means of producing reasonably permanent silver pictures. This is to be regretted, particularly as there are now so many more different processes in vogue and so many more different methods of toning. It may well be asked, what should be the test of permanency. It goes without saying that the best and most reliable test of all is that of time, necessarily a long and tedious one. Hence it is requisite to anticipate time by other methods, and the question is—What is the most reliable one? This question, one must confess, is more easily asked than answered.

We often read, when a new process of printing is brought forward, or when some modification in toning is advocated, that the author quotes as a proof of the permanency of the results produced by it, that prints have been subjected to strong light in a window for some months and yet show no signs of fading. Now, as a matter of fact, this is no test at all, for, as a rule, the pictures are exposed under conditions that are actually conducive to stability rather than fading. Light has little, if any, destructive action on a fixed print, and when the exposure is made in an ordinary room the conditions are those of dryness and a tolerably pure atmosphere. It is moisture and impure air that usually bring about the destruction of silver photographs. A pure and dry air is just what is conducive to the life of a silver photograph, by whatever process it is produced. The only circumstances under which it is likely for exposure to light to cause change is when the paper has been tinted with a fugitive coal-tar colour. An exposure in an outside show-case is a somewhat more trying test, inasmuch as, unless it is an airtight one, moisture is usually present.

It was said, a few years ago, that the most severe test a silver print could be put to was to expose it in a tunnel of the District Railway, and, steam traction being in vogue at that time, there was no question that if a print

withstood this test for a few months, or even weeks, it might be considered to all intents and purposes permanent. Those who exhibited specimens at the underground stations were fully aware of the destructive action of the fumes from the engines, unless the cases were made perfectly airtight in the first instance.

With reference to the light test alluded to above, Hardwich, in his sixth edition (1861), says:—"Bottles containing photographs suspended in damp air were placed outside a window with a southern aspect for nearly three months, but no difference whatever could be detected between them and others kept in total darkness." In another portion of the work he gives the following as a good test of permanency. He says:—"The most available and simple plan of testing permanence is to enclose the pictures in a stoppered glass bottle with a small quantity of water. If they retain the half-tones after a course of three months' treatment, the mode of printing followed is satisfactory." Although this simple method of anticipating the test of time was suggested so long ago,

it is questionable if any all-round better one is available now. Supposing, for example, one wants to test the relative stability of prints made by different processes, or toned by different means, we suspend them together in, say, a gallon glass pickle jar, with a little water at the bottom, and perhaps also with a small piece of sulphide of potassium, and secure the opening with a closely-fitting bung. The whole is kept preferably in a tolerably warm place for two or three months. Under these conditions most silver prints will succumb in quite a short time, and it will be obvious that those which withstand the deleterious action the longest are the most stable.

It may be agreed that photographs are never intended to be kept under such conditions. Yet the object here is to anticipate the action of time by subjecting the prints to their most destructive agents—damp and deleterious vapours—under enhanced conditions. There are other tests that may be applied, but the above is a simple one, and one that anyone without chemical knowledge may employ.

MATT SURFACE CARBON PRINTS.

HAVING experienced some difficulties with respect to obtaining matt surface carbon prints from ground opal as a temporary support, and having successfully overcome them, the following account of the means I adopted may prove acceptable to other photographers who find any trouble with this process.

In my first experiments I took the usual course of waxing the opal with one of the ordinary waxing solutions as applied in the double transfer-process to the temporary support, the result being that on development the film left the opal wherever the shadows were in contact with the whites, causing a frilling along the whole outline. With very careful development one or two prints were obtained only slightly frilled; but, on proceeding with these, the final support could not be removed from the opals with complete transference of the lighter tones. On consulting various books, and the instructions issued by makers of carbon tissue, the majority of which were annoyingly silent on the matter, I at length found some brief instructions for coating the opals with collodion, when matt surface prints were required, in place of the usual resinous waxing solutions.

As a matter of fact, the greasy waxing solutions are of no use in application to this particular process. Owing to the roughness of the ground opal the carbon print is separated into minute detached particles in the lighter parts which sink deeply into the grain, and, in the shadows, is held to the support mainly by the extreme projections of the roughened surface. To give a grip to the tissue in the shadows, and to ensure easy transference of the lighter tones, it requires on the opal a substratum or thin continuous film such as is given by collodion, albumen, or gelatine.

Collodion as a Substratum.

Opals for this process should be carefully selected. The grain must not be too coarse, but quite as fine as that on the ground glass of a focussing screen. Pumice powder applied with a wet cloth will remove all dirt from the surface of the opals, and if used regularly will keep them with a most suitable grain. It is necessary to take every precaution against scratching the surface, for each scratch will show as a glossy mark on the finished print. After cleaning and washing, and when quite dry, the opals are polished with French chalk, all particles of which must be dusted off before coating. The collodion solution consists of the following:—

Enamel collodion	1 part.
Ether	1 "
Alcohol	1 "

The opals are coated immediately before use, the solution being applied in the same manner as varnish to the negative, except that no heating is needed. In a few moments the coating will become set or jellified, but not dry, and when in this state the opal is plunged into a dish of cold water. For a time the collodion will repel water, having a greasy appearance, but in a few minutes this greasiness will disappear; when it occurs the exposed tissue may be placed in the water, squeezed down, being subsequently developed, and finished in the ordinary way.

By this process excellent matt surface carbon prints can be pulled from ground opal. There will be no signs of frilling or blisters; the detail in the half-tones will not "bleed" or wash away; the film will transfer easily, the prints being every bit as good as those from temporary support or by the single transfer process. The great drawback to the use of a collodion substratum is that of its cost, otherwise it answers the purpose admirably.

An Albumen Substratum.

A cheaper, and in many ways more convenient, substratum can be made by employing albumen. It is not, in some respects, equal to the collodion, for it has a tendency to release the whites, more especially when using new tissue, or when the negative is at all "contrasty." For all ordinary work from average negatives it is, however, quite reliable. The coating solution is made as follows:—

Albumen	Whites of three eggs.
Bichromate of potash	...	10 to 15 grains.	
Ammonia, .880	...	½ ounce.	
Water	...	20 ounces.	

The whites of the eggs are first thoroughly beaten with a whisk until quite frothy. The bichromate and ammonia are dissolved in a portion of the water, the beaten albumen added, and the solution made up to twenty ounces of water. The opals are prepared as previously in regard to cleaning with pumice powder and French chalk. A portion of the solution is then poured on the centre of the plate, and next spread over the whole surface by means of a glass rod.

When coated the opals are set up in a rack to dry, it being essential that the drying takes place in a strong actinic light. The light acting on the bichromate in combination with the albumen renders it insoluble in hot water, thus forming the necessary hard substratum upon which the tissue can be developed. Once hardened by the action of light, the coated opals

can be stored away, being at any time ready for use. Subsequent operations, squeegeeing, development, and transfer to the final support are conducted according to regular practice.

The final drying in this process must be very thorough. Unless the transfer paper is bone dry it will not leave the opal; ordinary drying in the atmosphere, except in the height of

summer, is not sufficient, and artificial heat must be applied to drive out every trace of moisture. My own practice is to leave the opals after transfer for twelve hours to allow the bulk of the moisture to dry out, and then to place them in a drying cupboard or before a fire until the paper strips from the support with little, if any, applied force.

JOHN A. RANDALL.

THREE-COLOUR NEGATIVES.*

PHOTOGRAPHY in natural colours requires, like monochrome photography, before all things (if first class results are to be obtained), good negatives; in fact, one might almost say that in three-colour photography direct perfect negatives are absolutely essential, for whilst in ordinary work a negative which is not quite correct can be made usable by reduction or intensification, these processes are almost excluded in three-colour, as they are at all times risky. In order to obtain a good negative, it is well-known that correct exposure and correct development are essential. The question now is: When is a three-colour negative correctly exposed and developed?

The "White" Test Object.

Most authors give as the test for correct exposure, that a pure white object must appear equally dense in all three negatives; equal times of development for all three negatives being assumed. From my own practical experience I cannot accept this axiom; indeed, I contend, that this rule is only exceptionally correct, and under absolute determined conditions. One of these conditions is that one has actually a "white" object, and this is not often the case. Thus, for instance, an object, which in itself may be white, can appear strongly coloured through reflection; a fact which only an expert eye naturally can detect. On the other hand, it is very easy for an object which is not actually in itself white to appear so, as in the presence of very brilliant colours, and in photographing the same, it will not show as such, and therefore in the two cases false conclusions as to the correctness of negatives may ensue.

Examples in Practice.

The two following cases, which actually occurred in practice, may be cited as illustrations:—To determine the exposure, a plaster bust was used in the ordinary way. It was proved later that the ratio of exposures was not correct, really because the plaster bust was a yellowish white. When looked at by itself, it appeared to be white, but as soon as another white object, for instance, a pocket handkerchief, was placed beside it, then at once the distinct yellowish tinge of the bust was seen. The negatives of this plaster bust ought not to be equally dense when correct.

An example of the second fault occurred in the case of a hall lined with blinding white and highly polished marble. It might be assumed that the three negatives should appear equally dense with correct exposure. This, however, was by no means the case. Why? Because the marble was not actually white, but appeared as though coloured. In consequence of its high polish, it reflected all coloured objects; for instance, the gold covered furniture, the bright brown parquet floor, and the result was that these colours could not and did not appear of equal density in all three negatives.

The Plate and Exposure Ratios.

But even when one has an absolutely white object, is this method of controlling the negatives only free from error under given conditions, namely, when a plate is used, on which the developer produces the same density as on an unstained plate?

If the colour-sensitised silver bromide is quite fresh or keeps

well, then it will develop dense. If, however, a plate has been kept for a long time, or does not keep well, such as bathed plates, then it is inferior to the undyed plates, it has altered chemically, with the result that the dyed bromide does not develop so dense as the undyed.

As now the negative through the red filter is made on the dyed silver bromide and the negative through the blue filter on the undyed bromide, it is clear that, in spite of correct exposures, the negatives cannot show equal densities in the lights, and thus conclusions drawn from this as to the correctness of the exposures would be directly false. I am in possession of negatives which, although made with the same filters and under the same conditions, still show decreasing density in the red-filter negative, the longer the plates are kept. The blue-filter negative, on the other hand, keeps its vigorous appearance so long as the change in the colour-sensitive film has not proceeded into decomposition. With bathed plates, especially, this observation can be made very well.

My observation, that the blue-filter negative is almost always denser, is confirmed by an article by Husnik in Eder's *Jahrbuch*, 1905.

On further grounds, too, can the advice as to equal density in the "whites" be shown to be erroneous. When the densest parts of the negatives are compared, it will be found a difficult matter, for the differences must be tolerably great to be visible with such great density. Therefore, I prefer to estimate the correctness of the exposure ratios from the shadows of the negatives.

Panchromatic Plates.

Intimately connected with the above phenomenon is the increase of the red sensitiveness of panchromatic plates. This increase is, as already said, only apparent.

Through this chemical change—which obviously must not have gone so far that it takes the form of fog—the plate behind the red filter works softer, and it is natural that the operator, in order to obtain the usual plucky looking negative exposes for a shorter time. As a matter of fact, he introduces more or less strong under-exposure, so that the negative looks pluckier and has more of the original appearance. Any practical use of this *only apparent* increased sensitiveness, can obviously not be made, since no one can say beforehand how far this change will proceed in a given time, or whether it has reached that point at which it will be apparent as fog.

A Black-Test Object.

As regards the determination of the exposure ratios, I actually use not a white but a black object; for instance, a matt black cloth in folds. Instead of the black cloth one may use a yellow, a red, or a blue cloth, the colours of which must be so chosen that the yellow cloth looks black under the blue filter, the red under the green, and the blue under the red filter.

In ordinary monochrome photography, as is well known, we decide whether the negative is correct when a black object appears clear in the negative, but still allows detail to be seen there. Three-colour negatives will be then correctly exposed, when the black cloth or the cloths, which appear black through the filters, are clear in the negatives, but are reproduced with

* A paper by Hans Schmidt in "Photographische Mitteilungen."

good detail. If the negatives in the said places are clear, but do not show details, then they are under-exposed. If, on the other hand, the negatives are fully exposed for these parts, then the exposure has been too long.

A white test object may, of course, be photographed at the same time as the black one. The former then becomes a good means of determining whether the development is correct. The negatives are then correctly developed, neither too thin nor too dense, when the densest parts of the same are still translucent.

A good three-colour negative has usually the character of a so-called soft harmonious negative, such as is desired for albumen printing; this, however, is not invariably the case. By the differentiation of the colours it may frequently happen that one of the three negatives presents a totally different appearance from the other two. This experience will be met with, for instance, in autumn landscape work, where generally the blue filter negative will appear glassy, whilst the other two negatives will appear normal.

Exposure Ratios under Different Conditions.

Another important question for practice is whether the ratio of exposures remains constant. This question I may answer with "No," for the ratio of exposures, with the same set of filters and the same emulsion, alters; it is dependent on the intensity and composition of the light that illuminates the object. The explanation of this is as follows: When a filter is examined with a spectroscope against a diffused sky, with the red filter, for instance, all may be cut out up to the D line, if, however, the same filter be examined against the direct sun, it will be found that under these conditions there is quite another absorption, for instance, perhaps the whole of the yellow will be transmitted. The filter in question will therefore be "more open." On these grounds, I am of opinion that filters which have been adjusted for studio work in diffused daylight cannot be satisfactorily used for outdoor work in summer sunshine. No attention has hitherto been called to these practical necessities, but in the course of my experience, I have found them absolutely necessary.

Landscapes especially, can only be well reproduced with narrow filters, although this gives a less favourable ratio of exposure. But in colour photography we must choose one of two methods, either the best colour reproduction, and somewhat unfavourable ratio of exposures (Professor Aarland's method) or a ratio of exposures as satisfactory as possible with a colour reproduction that is free from errors (Professor Miethe's method).

The Composition of Daylight as a Factor.

A further factor which influences the ratio of exposures is, as already pointed out, the composition of the light. It is a well-known fact in colour photography that in a yellowish light, sunlight, for instance, the orthochromatic action is much greater than in a diffused light. This also applies to exposures through filters. The composition of light is never constant. Days occur on which the light is very rich in red, but poor in blue rays, and so on. Very interesting studies may be made on this subject in the autumn. I have repeatedly observed that on a day when there was a strong mist the light was very poor in blue and green rays, whilst the red rays in proportion to the others were only slightly reduced. This is a fact that is generally recognised in photometry, and on account of this yellowish red light, such as petroleum, is preferred for light-houses.

That the ratio of exposures is also dependent on the position of the studio, must also be mentioned. It is a well-known phenomenon, that in many studios the light alters considerably in the course of the day. It frequently happens, for instance, that in the morning, a very warm, light, rich in yellow, is met with, whilst in the afternoon it is very "cold." Since the chemical action of light is not strictly proportional to these changes, the ratio of exposures must alter. If, for instance, the ratio for blue to red is found to be for the morning as 1:4, in the afternoon it may be as 1:4½. It is as well to take notes of these facts in making exposures for those processes in which the positive process allows no play. When the latter does occur, then these variations have not so much weight.

CLOUDING PORTRAIT NEGATIVES.

To photographers on the look-out for novelties as incentives to business, I would suggest that the clouding of portrait backgrounds of head and shoulder photographs, if neatly and artistically done, might be an excellent line. For whilst an extra charge can (if desired) be made for photographs so finished, the process practically costs no more than any other style, and the extra time occupied is fractional. Personally, I could cloud numbers of cabinet backgrounds at an average speed of from two to five minutes per negative. And another point to be considered is that the semi-fanciful finish obtained harmonises well with mounts suitable for photographs for presentation.

The Modus Operandi.

Varnish the retouched (or otherwise) negative with what is known as matting varnish, of which the following is a good formula, viz. :—

Seed lac	2 ounces.
Sandarac	2 ounces.
Oil of lavender	½ ounce.
Castor oil	½ to 1	ounce.
Methylated alcohol	40 ounces.

The addition of some powdered glass will facilitate the solution of the gums, and gentle heat usually has to be used also. When dissolved allow to stand for several hours, then decant, and filter once or twice (an advantage). Great care must be used to ensure both negative and varnish being absolutely free from dust, as it is fatal to success in this class of work. After the

negative is cold rub the varnish gently down with the fingers, which have been previously dipped in powdered resin. When a uniform matt surface has been obtained wipe off with cotton-wool and keep the latter for further use, as dusting the negative with this impregnated wool is infinitely superior as a preliminary to dipping the fingers in powdered resin.

Handling the Negative.

The negative is now ready for clouding, which is done with the aid of a stump (a tint-stump for broader surfaces) and some electrotypers' plumbago.

For the stump choose a very firm-pointed paper, about half an inch or more in diameter, and rotate the pointed ends on a piece of fine glass-paper until they present a perfectly smooth and silky appearance with fine points. A tint-stump can be made by screwing a small flat button on to the end of a pen-holder, and covering the knob thus formed with two or three thicknesses of ordinary surgeon's lint.

Place some of the plumbago upon a washleather pad, and work it well into the leather with the ordinary stump. When the latter is evenly charged (not too heavily) apply it over the background of the negative so as to form clouds "in negative," the best kinds for the purpose being those known to meteorologists as cumulus, cumulo-stratus, and "scud." It is important to make the highest lights in the clouds less intense than those of the features, otherwise the artistic quality of the production will be lost, and the picture look "made up." Let the work, therefore, be of a subdued tone, the highest lights equalling in

depth the middle tones of the face, and placed on the shadow side of the latter. By doing so the portrait will be thrown out, and if the clouds on the lighter side of the face are only faintly portrayed it will give the effect of light striking them after it has passed the sitter, and will cause the background to build up and harmonise with the rest of the photograph instead of detracting from it. Again, it sometimes happens (if the clothing is of a similar tone to the background) that the shoulders seem to merge into it, and when this may be undesirable it is easy to bring them into relief by clouding the latter over their immediate vicinity, any overlapping of the work being afterwards erased

with a retouching knife, used so as to glide over the varnish without scraping it.

Vignette "Clouded" Negative.

Of course negatives finished in this method should (usually) be printed solid, although it is possible to obtain some very nice results if they are vignetted, provided the retoucher has had the latter method in view when retouching. The work should have a soft, fluffy, but not woolly appearance, the higher lights being of very narrow or small and the shadows (formed by leaving the part alone) of greater and broader proportions.

ARTHUR WHITING.

A FIFTH AVENUE ESTABLISHMENT.

THE new partnership into which, as we reported a few weeks ago, Mr. Rudolf Eickemeyer, jun., is entering in New York is with Mr. Charles H. Davis's, whose firm thus changes its original title of Davis and Sanford. Mr. Davis has long been the moving spirit in

At the most fashionable part of Fifth Avenue, where more than fifty thousand people are said to pass every day, on the top floor of a stylish office building, you will find the famous studio of Davis and Eickemeyer, successors to Davis and Sanford.

A huge reception hall, with a skylight decorated with evergreens, greets the visitor. There are pictures everywhere—on the richly carved tables of Flemish style, on the walls, in showcases—photographs, portraits, pictorial bits and gum prints, pastels, miniatures, and oil paintings in frames of every size and period imaginable.

I send in my card, and while waiting turn over the pages of an edition de luxe of Sir Henry Raeburn's paintings that lies on the table. Mr. Charles H. Davis enters—a striking personality, genial, unassuming, matter-of-fact—with that peculiar twist and slight stoop in his figure which men of will power and restless energy invariably have.

"May I look over your prints?" I ask. He is only too willing. The portraits present a remarkable average of excellence. They are all made in the academic style, clear and distinct, and have that peculiar sympathetic quality which tells even the stranger that they are good likenesses.

"You do not have much sympathy with the tonalists?"

"No, they are not to be taken seriously. They are a joke." His remarks are always pert, to the point, and he utters them with peculiar emphasis, but uses gestures rather sparingly.

"I believe in clear lighting," he continues. "I want the entire figure, and try to give it as much variety as possible. I have no patience with these men who only restrict themselves to bust portraits. There is no chance for composition in them. I work on the same principles as the painters do. I strive for line, a natural attitude. You will find that all my subjects are correctly poised. Never make a mistake in that. You will see that I pay quite as much attention to the position of the feet as I do to the arms and the face."

The standing figures that he shows me are of astonishing variety. They show decorative simplicity and exquisite precision of line, and they are posed in a way to show repose without loss of active suggestion.

"Look at the cast of Diana's head over there. Do you see how the oval of the face, slightly turned sideways, is set upon the neck. The lines of the neck and face flow together in a curve. I pose all my heads this way. It is the classic standard. You will not find a single head that does not carry out this idea. You will also notice that I give particular attention to the hands. I do not know of any other photographer who carries out these ideas, at least not in the same way as I do."

I perfectly agree with him. He is a master of hand posing. He

his establishment in Fifth Avenue, and it may, therefore, be of interest to make some few extracts from the record of an interview with him which we find in the American "Amateur Photographer." —Eds. B.J.P.]

always manages to get the hands into the same plane as the face, and they never look out of place or disproportioned.

"Do you believe in retouching?" I next inquire.

"As little as possible. But I keep in mind that my class of clients insist on the removal of skin blemishes. I do not believe in too many corrections on the negative. I strive to overcome all shortcomings by a system of lighting that flatters my sitters. I seize directly on their best points, and pose them in such a way that all their natural defects are hidden or subdued in contradiction to the usual method of over-retouching."

"Then you indorse my opinion that the principal thing in photography is the arrangement of the subject before the picture is taken. You do not believe in taking haphazard shots and correcting them afterward?"

"There are no accidents in my work," he answers with peculiar emphasis. "I know exactly what will be on the plate, and I always work toward the ideal as closely as the nature of subjects and gowns permit. You may also state that I am a skilled hairdresser, and I make use of the knowledge right along during the sittings. There is hardly a day that I am not called upon to arrange the hair of some lady, to build up some elaborate structure or to produce a picturesque effect. I also advocate the use of simple gowns, that do not go out of fashion as quickly as tailor-made costumes. It is of advantage to the photographer to portray a lady in a gown that belongs to no special period, as it will enable her to order prints from the same negative even after a lapse of ten or twelve years. I am sometimes asked to select the dress for a lady, and visit her home for that purpose, or let her bring along five or six dresses to choose from. Drapery, of course, would be more picturesque than anything else, and I sometimes succeed in persuading them to make use of it."

Mr. Davis is remarkably free from all idiosyncrasies of contemporary camera work. He has ransacked art, but only to become more efficient in his profession. His ideals are accurate facial expression, clear lighting, simplicity of pose, naturalness and unconscious grace.

The best or most ideal results in photography can be achieved only when the photographer and his subject are thoroughly in sympathy. As it is extremely difficult for any photographer to be thus in sympathy with many subjects, differing as they do greatly in character, it follows that perfect photographic work must be very limited in quantity, unless the photographer can by cultivation and some degree of self-abrogation, establish such a bond. Charles H. Davis, as well as his new associate, Rudolf Eickemeyer, has this appreciation for the sitter. They see something of interest in every person; and this real sympathy, which so many photographers lack, should assure the studio now, as in the last two decades, success with the large masses of the intelligent public.

SAVING PHOTOGRAPHIC WASTE.

[The current issue of "Wilson's Photographic Magazine," in quoting a recent article from our columns on the question of the recovery of silver residues, publishes in connection with it some notes on the practical methods of residue saving as discovered in the course of a lengthy studio experience. As we have often pointed out, a great deal depends on the scale on which operations are carried out, but as the question is one on which queries are often addressed to us by our readers, we may quote from the article, which is by the well-known writer, Mr. A. J. Jarman.—Eds. B.J.P.]

The subject of saving the waste material that contains the precious metals has been written and rewritten many times. It might be considered unnecessary to treat upon the matter because it is thought that the subject is well known and understood. Such, however, is not the case. There are many photographic establishments to-day in New York City, and doubtless in scores of other places, where the waste is not taken into account. Then there are establishments where the silver waste is saved and the old toning baths and platinum solutions are thrown away.

The editor of one of the photographic journals asked the writer a short time since whether it was not possible to precipitate the silver from waste solutions without the use of that very objectionable chemical, sulphide of potassium, or liver of sulphur, as it is sometimes called. The latter name was given by the alchemists who discovered it. Yes, it is possible to precipitate the whole of the silver by means that will not be objectionable in a photographic establishment. They will be here described.

To Save or Not to Save Apparatus and Materials.

In the first place, procure a kerosene oil barrel, or a wine barrel, remove one end, then wash the barrel out with hot water and drain, then bore a hole about one foot high from the bottom, and insert a wooden tap or faucet such as is used in a vinegar cask or a cider barrel. Mount the barrel upon a strong wooden stand or trestle, and provide a wooden cover. The object of the cover in this case is not for the prevention of any injurious fumes escaping, but to prevent the dropping into the barrel of anything of use and value. Pour into the barrel any kind of silver solution, such as the fixing solution that has been used for negatives (this solution is always rich in silver); also the first making of the silver prints and the hypo solution that the prints have been fixed in. Place in the barrel about eight or ten pounds of clean scrap zinc, cut into strips about three inches wide and a foot or eighteen inches long. As soon as the barrel is about half-full of these solutions pour into the mixture about a pint of common muriatic acid (spirits of salt). Stir the mixture with a long strip of wood, replace the lid and allow the mixture to stand. Continue to add the waste solutions until the barrel is full, or nearly so, when a few ounces more of acid may be added. If allowed to stand undisturbed for two or three days the whole of the silver will have been precipitated in the form of metallic silver and sulphide, due to the liberation of sulphur from the hypo upon the addition of the muriatic acid. The clear liquid may now be drawn from the barrel by the wooden faucet, and thrown away. Continue to save the waste in this manner until the precipitated material has nearly reached the faucet. Then make up two or three bags of calico, about eighteen inches long and eight inches wide. Arrange a piece of string in the top so that they can be suspended from a rod placed across the barrel. Scrape up the precipitate with a small enamel saucepan, pour it into the bag until the bag is full. Proceed in like manner with the second bag. Allow them to drain thoroughly, say for the night, now tie the mouths of the bags up and all is ready to send to the refiner.

Small quantities of nitrate of silver solutions may be thrown into the barrel, but if the quantity of nitrate of silver solution is large, it will be advisable to precipitate the silver as chloride, in a large

stoneware crock, by the addition of muriatic acid (common), and not by means of common salt, because if the salt is added in excess, a portion of the chloride of silver which is formed will be dissolved, forming a clear solution of the double chloride of sodium and silver. A solution of common salt is all right, providing you know the exact strength of the silver solution, and figure out the right quantity of common salt to use. If not, the chances are that much of the silver will be lost for the reason given. When emptied the barrel should be replenished with pieces of zinc if found necessary. Always add the muriatic acid a few ounces at a time, because the liquid in the barrel is apt to effervesce and foam up, owing to the presence of gelatinous matter from some of the papers. If the barrel can be kept out of doors the sulphide of potassium can be used, but for indoor use the above method cannot be surpassed.

Gold Residues.

In saving gold waste from the old toning solutions the usual plan is to employ a five or six gallon stoneware crock with lid. Place in it a handful of protosulphate of iron. Pour into this the discarded solutions and stir up occasionally; but to get the full effect of this, the crock should be kept in a warm place, or the old solutions made hot occasionally when thrown in. If a few strips of zinc are placed in the crock in addition to the protosulphate of iron, and a few ounces of muriatic acid added occasionally, there will be no need to heat the liquid, nor to stand it in a warm place. Every trace of gold will become precipitated. The liquid will froth up sometimes upon the addition of the acid for the same reason given for the silver solution. When the crock is full, decant the clear liquid carefully, so that no precipitate is lost. Continue operation for about one year then wash out the crock with its precipitate, pouring this into a filter paper that has been fitted into a large funnel. Be sure and place a small piece of absorbent cotton across the apex of the filter paper. This will form a strengthened support for preventing the filter paper from breaking. As soon as the precipitate is well drained it may be dried and sent to the refiner. Any other waste gold solution, such as the washings from bottles containing deposited gold upon their sides and spoiled gold solutions should all be thrown into the crock.

All these little points should be attended to in a photographic establishment, for it costs no more labour to cast these old baths into the saving vessel, than it does to throw them down the sink. All kinds of silver paper, whether toned or not, should be saved, and packed in a sack or in a sugar barrel when sent to the refiner.

Platinum Wastes.

Platinum waste of every description should be saved by the photographer; all the scraps of unused paper, as well as discarded prints and the print trimmings, old or disused developing solutions, and the first acid clearing liquids in particular. The value of platinum to-day is twenty-two dollars per ounce, gold being twenty dollars and eighty cents, and silver about forty-five cents. The refiners of platinum allow eighteen dollars per ounce for the metal obtained from photographers' waste, so it will be seen from this what is to be gained by the exercise of a little care.

The best way to save the wastes of platinum in addition to the paper scrap is to employ a large stoneware crock, anything from five to ten gallons. Those of an upright form are best for metal; fitted with a stoneware lid. Place in the crock three or four pounds of scrap zinc as previously described. When any number of platinum prints have been developed and cleared in the usual muriatic acid solution, pour all of the first clearing solution into the crock. If the number of prints has been considerable, throw in the second acid bath as well. Chemical action at once takes place, the acid attacking the zinc as well as the small quantity of chloride of the platinum salts. The

zinc strips become blackened, by the deposit of metal platinum in a finely divided state. Eventually this falls to the bottom of the crock, together with iron and other bodies. By the next day all the platinum has been thrown down. Continue the adding of these acid solutions, as well as any discarded platinum toning baths used for toning paper prints, until the crock is full. Stir the contents well with a strip of wood and allow to subside. This usually occurs in a night. The clear liquid may now be bowled out with a small saucupan and thrown away, of course taking care not to disturb the precipitate, which looks like grey mud. All old or discarded developing solutions may be thrown in with the rest. It does not matter whether the developers and clearing solutions have been employed for black or sepia.

It may be found necessary occasionally to add a few ounces of muriatic acid to the contents of the crock, to aid precipitation when the acid baths have become almost neutral by the admixture of much of the developer, and through the addition of old developers. Stir the mixture up every night. This will insure the deposit of all the platinum.

Collecting the Platinum.

If there is much work done in the production of platinum prints, it is advisable to employ two crocks; it will well pay the photographer to do this. After a month's or six weeks' saving the precipitate may be removed. To accomplish this employ a large glass funnel, about one gallon; place at the bottom a drawn-out piece of absorbent cotton about the size of the palm of the hand; fold up a piece of stout blotting paper to act as a filter; place a fine strip of the same paper, folded, against the sides of the funnel, then fit in

the folded blotter; bowl out the precipitate; fill up the funnel which should be placed in a six-inch hole in a piece of board across the top of one of the crocks; continue the filling of the funnel until it is full, or as soon as the filtering is complete. The whole mass may be stood aside to dry, or placed in a box that has several thicknesses of old blotting pads upon the bottom.

Continue to save the precipitates in this way until there is about twelve pounds of this precipitate which in a large establishment will take about three months to accumulate. It may now, together with the paper cuttings and waste, be sent to the refiner, where it will be found that the returns made will form an agreeable surprise. If the number of prints have been about three hundred per day, of varying sizes, and the directions here given have been carried out correctly, especially if the prints made have been in black, and not many in sepia, it will be found that about fifty dollars will represent the sum returned for the platinum waste alone. If saved for a year in varying quantities, together with the gold and silver, where some five or six hands are required to turn out the printing, the returns for waste may be expected to realise from one hundred and twenty dollars to one hundred and fifty. This statement is based upon actual experience in the saving of waste upon the lines here described.

The value of precious metals that is allowed to waste will amount to thousands of dollars in many large cities, where it is deemed today in many establishments that the returns are not worth the trouble to save. Platinum paper contains a large percentage of the metal, and when it is considered that every ounce of platinum will return the photographer eighteen dollars, it will be seen that here is a source of income that is well worth giving attention to.

RECENT INTRODUCTIONS IN COLOUR PHOTOGRAPHY.

In colour photography more than in any other photographic process methods are in a transition state, and no one will maintain that there are signs of any process or processes fixing themselves permanently in practice. Yet it is desirable to record what is claimed for new processes as they arise, and we may therefore conveniently do so in several instances by quoting, in whole or in part, from several articles in "Penrose's Pictorial Annual," reviewed on another page. In these contributions the inventors of processes or

modifications of processes state their own cases, making claims which cannot be accepted in every case without qualification. However, as our duty is to give our readers the opportunity of considering what is being done, we may allow the contributions of Mr. C. G. Zander, Mr. John H. Powrie, Captain Lascelles Davidson, and Dr. E. F. Grün to create their own impressions. The handsome new volume of "Penrose's Annual" may be consulted for the articles *in extenso*, and for the supplemental illustrations which there accompany them.—Eds. B.J.P.

THE COMPLEMENTARY COLOUR REPRODUCTION PROCESS.*

GREAT as was the future unanimously predicted for three-colour printing when it made its public appearance and caused a sensation in the printing world, some prophesying the early extinction of chromo-lithography by the process of photo-mechanical colour printing, the early results were far from perfect. It was contended, however, that the process was then in its experimental stage, and that there were technical difficulties and defects in its practice which had to be overcome. Amongst these difficulties were photographic plates comparatively insensible to various colours (particularly red), incorrect colour filters, unsuitable printing inks, inexperienced printers, and the unsatisfactory method of printing from half-tone blocks.

Fifteen years or more have passed, and when looking back upon the early productions of three-colour printing one cannot help being disappointed at the comparatively small progress which has been made.

Most of the above-mentioned technical defects and difficulties have been overcome. We now have panchromatic dry plates, and also emulsions, with a practical perfect sensibility to the whole range of spectrum colours. The action of colour filters has been studied by many patient observers, the inks have had their share of attention, and can be made practically perfect in hue and proportionate density. The half-tone blocks, especially those of fine grain, have been very much improved in the matter of sharpness of detail and gradation of tones. The printers have also learned and fairly

mastered their lesson. We must mention the fine-etcher, the skilful artist whose hand work overcomes many of the mechanical defects of three-colour work. It is his business to remedy the incongruity of the filters and printing inks, to correct photographic errors, and to make the best of the limited colour-range available in three-colour work, in order to approach as near a facsimile of the original by hand work, as is possible in the process; his importance in the production of three-colour half-tone blocks is now fully recognised, and quite a generation of highly-trained and skilled fine-etchers has grown up. As a matter of fact if it had not been for the fine-etcher, the three-colour half-tone printing process could never have attained to the commercial importance which it has done.

Considering the progress made in the perfection of the materials, the overcoming of technical defects, the improved skill of the block maker and printer, we repeat that the results obtained, even with the best three-colour blocks under the most favourable conditions, are disappointing, and no judge of art would class the three-colour print amongst artistic productions—they find no place in our best print and picture shops. To enumerate a few of the defects, we would mention:—

The limited range of colours—there are no pure greens obtainable, but instead an offensive juxtaposition of blue and yellow dots, no pure blues in skies, no brilliant crimsons, violets, no pure blacks or homogeneous greys. There is always one predominant hue obtrud-

* British and foreign patents pending.

ing, mostly a dirty purple or hideous green. Most of the brilliant colours can, of course, be dispensed with in the reproduction of paintings, but in commercial work, such as, for instance, the reproduction of drapers' pattern cards, carpets and the like, three-colour work has proved itself an utter failure.

In his studies to find ways and means of overcoming the defects and shortcomings of the three-colour printing process, the writer of this article reasoned that if the materials were perfect or nearly so and yet the results were imperfect, the cause of the failure must lie in the philosophy of the process. It was with great reluctance that, failing everything else, he at last set himself to find out whether the Young-Helmholtz theory of colour vision on which the three-colour process is based was really the best basis for photo-mechanical colour reproduction, or whether some other colour scheme worked out would produce better results. The writer asserts that he has found another colour scheme which in actual practice yields far superior results to the famous Young-Helmholtz colour theory, as far as the range of colours and other effects are concerned. The Young-Helmholtz theory of colour vision assumes three fundamental colours, by mixture of which in various proportions all colours in Nature are to be matched. The theory, on which the writer bases his process of photo-mechanical colour reproduction assumes and uses not three but four fundamental colours, *viz.* :—red, yellow, green, and blue, by mixtures of which in suitable proportions any colours in Nature can be matched or reproduced. The hues of these four fundamental (or monochromatic) colours, red, yellow, green and blue may in popular terms be approximately be described as follows:—

Magenta Red, Emerald Green, and
Lemon Yellow, Ultramarine Blue.

It will be found that magenta-red (we use this name for the lack of a more scientific one) is one of the constituent colours of spectrum red (magenta-red + Yellow) and also of Spectrum Violet (Magenta-Red + Blue).

The four fundamental colours can be grouped into two pairs of complementary colours, *viz.* :—

Red and Green,
Yellow and Blue,

so that when the elements of either pair are mechanically mixed as pigments, by printing or staining, they produce black, while the effect of their optical combination produces the sensation of white light.

It will at once be seen that the complementary colour reproduction process does not consist of a mere addition of green to the yellow, red and blue of the three-colour process, but is based on a scientific adjustment of the above-mentioned four fundamental colours, so that they form two pairs of complementary colours as indicated.

The complimentary colour scheme described above is applied to photo-mechanical colour reproduction. The two pairs of complementary colours (red and green) and (yellow and blue) are used as printing or reproduction colours. The complementary colour reproduction process undoubtedly offers many important advantages over the non-complementary colour schemes (yellow, red and blue), or (yellow, red, blue and black or grey) at present in use in photo-mechanical colour reproduction.

Amongst such advantages are the following:—

1.—The range of mixed colours which can be produced by the Zander Complementary Colour Reproduction Scheme is very largely extended, and comprises the whole range of spectrum colours, extra-spectral purples, dense pure black and homogeneous greys. Among the pure colours obtainable by this process may be enumerated in

particular pure brilliant magenta and purples, emerald green, ultramarine blue, violet, colours which cannot be produced in three-colour work.

2.—The reproduction of dense pure black or homogeneous neutral or tinted greys can be accomplished with ease, owing to the fact that either of the proposed two pairs of complementary reproduction colours are already sufficient to produce black (or grey) which is impossible to do with any two non-complementary colours, or even the three colours used in photo-mechanical colour-printing at present.

No pure black can be reproduced at all in three-colour printing.

3.—In printing, the reproduction of any given subject by two pairs of complementary colours (instead of three non-complementary colours alone or with the addition of black or grey) will prevent great variations in the several impressions, particularly in long runs, owing to the fact that slight variations in the impressions will not obtrude themselves as much in an *ensemble* of four colours as in three. It is well known to every chromo-lithographer that the greater the number of plates requisite to reproduce a given object, the fewer will be the variations between the finished prints.

4.—A more accurate reproduction of the original is unquestionably possible than by the non-complementary colour processes at present in use, owing to the greatly extended range of the single reproduction and mixed colours.

5.—The hand work or fine-etching, by far the costliest part of the present processes of photo-mechanical colour reproduction, will be reduced to a minimum, as not only the reproduction colours among themselves, but also the photographic colour records and the reproduction colours, stand in more rational and scientific relationship. As mentioned before, the reproduction colours consist of two pairs of scientifically grouped complementary colours, while the relative colour negatives, broadly speaking, represent photographic monochromatic records of all the spectrum colours, complementary to the respective reproduction colour. Practical workers know that this is not the case in three-colour work, and has (with the limited colour range) to be compensated for as far as possible by the skill of the fine-etcher.

The standardising of colour-filters and reproduction colours, so long hoped for aid aimed at in three-colour work, becomes an accomplished fact in the complementary colour reproduction process, in which filters and reproduction colours are carefully and scientifically selected and adjusted, and are of standard hues which may be used with equal success on any subject by any blockmaker or printer respectively.

The working of the Zander Complementary Colour Reproduction Process requires no special plant beside that which is necessary for working the three-colour process, or which is found in the establishment of every three-colour blockmaker or photographer, the only addition being a set of four special colour filters. These colour filters materially differ in hue from those used in three-colour work, and their correct chromatic construction has been a matter of great care and patient study in order to compensate for the defect of the panchromatic photographic plates. The actual practice of the process offers no technical difficulties whatever to the expert skilled in three-colour work. The invention distinguishes itself by its great simplicity and its wonderful results.

The Complementary Colour Reproduction Process explained above is applicable to every process of photo-mechanical colour reproduction, such as typographic block-printing in half-tone, line and the like, photo-lithography (both from stone and plates), collotype, photogravure, Woodbury-type and the like, also for reproduction by superposition of transparencies in colours. C. G. ZANDER.

PRACTICAL HELIOCHROMY FOR PROFESSIONAL AND AMATEUR.

To those who are familiar with the various processes of natural colour photography, the recent developments that have been made towards securing a practical method of making transparent photographs in natural colours will be read with considerable interest. The process I am about to describe is a modification evolved from the colour line screen which was first suggested by Louis Ducos du Hauron in 1868, in which the colour was applied to the plate in fine parallel juxtaposed bands of the so-called primary colours. The process was subsequently developed by Dr. Joly, known as the Joly process, and also by James W. McDonough, of Chicago, known as

the McDonough process; and the results of considerable artistic merit were attained in both processes.

The lined appearance of the plates was rather objectionable, being from 250 to 300 to the inch, and the difficulties of being able to make the plates and screens coincide were very great. Further, the cost of ruling the sheet of glass, with the colours having proper light absorptive values to obtain satisfactory results, was prohibitive.

The plates produced by the Powrie-Warner process are structurally different, and the manner of using them is greatly simplified.

Sheets of ordinary negative glass are coated with bichromated gelatine, and exposed to the light through a negative plate of transparent and opaque parallel lines. The light passing through the transparent lines of the negative renders the gelatine insoluble in warm water, the unexposed portions washing away, thus securing upon the glass colourless gelatine lines, which with the plates now in use are from 1-600 to 1-1000 of an inch in width.

The plate is then immersed in a colour bath of a suitable green dye, and then in subsequent baths to render the colours stable, washed, and dried. The appearance of the glass is a delicate green tint. It is then recoated over its entire surface a second time with the bichromated gelatine, and again exposed to the light through the opaque lined negative, taking the precaution to have the green lines protected by the opaque lines in the negative, and also one-half of the remaining unexposed surface.

The plate is treated in a similar manner after this exposure as for the green lines, except that a red dye is now used, and the plate is rinsed and dried as before. The appearance of the plate is yellowish in tone. It is then recoated a third time, again exposed, and passed into a bath of violet blue dye. This gives the plate a neutral tint from the recombination of the three elementary colours. The surface being completely covered without overlapping of the edges.

It is possible by this photographic printing operation, with special machinery for aligning the plates and printing them automatically, to obtain remarkable uniformity. The increased fineness of the colour lines renders them invisible to the eye, and registration of the lines with a transparency would be impractical.

The next operation is that of coating the plates with a panchromatic

emulsion, when they are ready to be exposed in an ordinary camera, developing and fixing in the usual manner, and obtaining a negative in colours. It is obvious that the exposure in this case must be made through the glass. These negatives show the red rose as green, the green grass appears purple, yellow flowers appear violet, and violet appears yellow, the colours, as well as the lights and shades, being reversed.

In order to understand this, I should explain that light reflected from a red object passes through the red lines in the Florence chromatic plates, the red rays of light being absorbed by both the green and violet-blue lines, and on development and fixation it is found the silver is deposited only upon the red lines, leaving the green and blue lines transparent over the particular area representing the red object, giving it a greenish blue colour.

By the use of Florence chromatic transparency plates and films, lantern slides and window transparencies may be made in the ordinary way, either by contact printing, reduction, or enlargement with the camera, no regard to registration being necessary, as the lines are practically disregarded in this process, being merely a convenience for the manufacture of the plates only. The transparency plates differ from the negatives only in the use of a transparency emulsion upon the lined plates, which is also panchromatic.

A thin sheet of suitably tinted transparent material accompanies each package of plates and films to equalise the light values of the different colours. No additional apparatus or special skill is required other than is necessary in making the ordinary black and white negatives and slides, to secure them in colours.

JOHN H. POWRIE.

THE LATEST ONE-PLATE COLOUR PROCESS.

THE system I have devised, the experimental part of which has been so admirably carried out by my respected friend, Mr. Friese-Greene, is essentially a one-plate process, that is to say, only one negative (of good gradation and density) is required to make a beautiful print in colour. This feature alone makes the process unique and of a far-reaching character, and when it is further considered that no special apparatus, colour screens, or difficult colour process are required, and that a bromide print in colours can be produced and finished within ten minutes, the simplicity of the process can be gauged. In order to attain first-class results, and as true as possible to nature, the negative must be fully exposed and developed to a good density.

The densities (representing colour in monochrome) should be as nearly as possible as follows:—

White in the original scene should be opaque in the negative.

Blue should be semi-opaque.

Green should be of middle density.

Yellow should be of middle density.

Red should be of faint density.

Black should be of clear glass.

It will be seen by the above remarks that the densities of the negative play an important part in the process, but the process offers such scope and latitude in correcting errors during the redevelopment (which is accomplished in daylight) in colour that practically any clear good negative can be printed from. Further, the result seen from such a negative would be far more artistic and pleasing

than a print made in what I may term now the somewhat uncommercial three-colour process prevalent at the present time. The next important feature in the process is that the colours are developed, or redeveloped up in the print, which makes the finished result in colours very permanent, besides giving the operator, if artistically inclined, enormous control over the colour during redevelopment. To make myself clear on this point, I will give a short description of the *modus operandi* of the process.

First of all, a bromide print is printed, developed, washed, and fixed in the usual manner from a negative. The print is now thoroughly washed in water for five minutes and then bleached in a special bleaching compound, and when bleached the print is rinsed in water and the redeveloping colour compounds applied all over the print.

If the red developing compound is applied first only the red and yellow deposits in the print will be affected, and will develop up to a red. The blues and greens will not develop up until a developing compound for such colour is applied to the print, when the colour will be gradually redeveloped and built up in the deposit of the print. The highest lights (whites) do not take any colours and wash quite clean, unless the redevelopment has been carried on too far. It is only during the period of redevelopment that a bromide print shows power to select or repel a colour or colours, after which it becomes stained and untrue; but the latitude allowable in procedure before this stage is arrived at is very great.

CAPTAIN LASCELLES DAVIDSON.

THREE-COLOUR PRINTS.

During the current year, in conjunction with Mr. Albert Smith, of Southwick, I have been directing my efforts towards producing a simplified method of translating the three-colour negative record with a positive colour record, and I am happy to say that it is now possible to produce a result in a far more simple manner than has been hitherto available. The principle of this method lies in the fact that the gelatine surface of the ordinary lantern slide, bromide opal or bromide paper is capable of receiving three printings in successive colours. Briefly, the method is as follows: To those who have made a study of the Sanger-Shepherd process, the details will be quite easy to follow. In the first place, a blue-toned base is made which may be lantern slide, opal plate, or paper. This blue-toned base is then sensitised with bichromate solutions, dried and printed under the

green screen negative in the ordinary way. The excess of colour is removed by washing in cold water after the Jumeaux-Davidson method, leaving the gelatine intact upon the plate. This plate is now resensitized with bichromate, and a third printing under the minus-yellow screen negative gives the complete result in perfect colour value, this doing away entirely with the necessity of superimposing successive layers of films. For lantern-slide production this method gives absolutely perfect results. For portraiture upon opal plates the method gives results occasionally uncertain, but in about 25 per cent. perfect; by adopting a ferricyanide sensitized opal plate the proportion of successful results is much greater, and probably a little further experimenting will result in quite certain results. The difficulty at present is to get a reliable blue. The red and yellow printing present no obstacles. Any photographer trying

this method will find that, provided the exposure of the bichromatised print is not carried too far, and with a recently sensitised print the exposure in good sunlight is not much more than five minutes, the result with red staining is most accurate. The subsequent print-

ing for the yellow staining must be very brief, as the effect of the bichromate and the exposure to the same is inclined to degrade the red, but if sufficient care is used this can be avoided.

EDWARD F. GRÜN, L.R.C.P. (Lond.).

A NOTE ON DIFFRACTION GRATING REPLICAS.

(A Communication to the Royal Photographic Society.)

About the year 1898 I became possessed of a "Rowland" diffraction grating of 14,438 lines to the inch, which I fitted up for solar prominence observation and other work. During some experiments with the grating it occurred to me that possibly transparent copies might be made if only a suitable medium could be found, and with this object in view I made a number of experiments with collodion, etc., and a variety of mounting media, after first ascertaining that no harm would come to the grating. I eventually adopted a clarified solution of celluloid in amyl acetate and nothing but pure water as a mounting medium, and with the exception of certain minor details have seen no reason to alter my method, which is briefly as follows:—

Ten grammes of the clearest celluloid, shredded, are added to 700 per cent. of amyl acetate, and when quite dissolved the whole is slowly filtered through cotton tow, when a very clear solution is obtained. About 2 per cent. of this solution is poured on the surface of the grating, which is some 2.5 in. in diameter (after the same has been very carefully levelled) and then allowed to dry. Special precautions must of course be taken to prevent access of dust, as far as possible, and to secure uniform drying, as upon this latter depends the optical perfection of the film; its thickness is about 1-6000 of an inch. The surface of the glass upon which the film is to be mounted is now cleaned and left standing with water upon it. The film, which by the way takes about a day to dry, is now moistened, and, in a very short time, being found to be easily detachable, is stripped and placed face downward upon the wet surface of the glass. After getting rid of the bulk of the water by tilting, the film is generally allowed to dry spontaneously, but I often hasten the process by using blotting paper of a particularly smooth kind, and in this way the drying is only a question of a few minutes. The edges of the grating are now pared round and fastened down by means of the same solution, a camel-hair brush being used for this purpose. Before this latter operation, however, the gratings are tested in the spectroscope, and if found optically good are placed face down upon the original grating or on a similar grating. Now, as celluloid shrinks in drying and not always to the same extent, due to slight differences in temperatures and quantities of solution, the lines are somewhat closer on the replica than on the original, and a little consideration will show that the interference bands produced by contact of the two surfaces are a measure of the shrinkage, and all one has to do is to add to the original number of lines to the inch to that of the interference lines to get the correct spacing in the replica. The shrinkage varies from about 50 to 100 to the inch.

Whilst the film is still on the grating it is my usual custom to place it behind a sodium flame, when the condition of the surface shows at once whether the drying has been uniform or not. Several rings appear at times approaching the centre, and the replica is then known to be worthless as the shrinkage will not be uniform when mounted.

It may appear at first sight that this method of mounting is only a very temporary one; and so it is in a sense, as the films can be taken up and remounted with ease, but really after a time the films become adherent indeed, and great difficulty is experienced in removing old films except by dissolving.

In my original experiments the method of mounting the film with the grating side to the glass was tried in the way now used, I believe, by Mr. Ives (without, however, any backing), but the results were not satisfactory, as interference due to the film took place, and the definition was not improved in any way.

I may here say that I have brought the particulars above described before the Manchester Literary and Philosophical Society from time to time as may be seen by looking up the memoirs and proceedings.

In the year 1900 I applied these grating replicas to colour photography and read a paper on the subject before the above society, and in a patent I took out for the combination a claim is also made for a method of producing grating replicas by first giving the grating a coating of oil, and in Mr. Wallace's article in the "Astrophysical Journal" for September he takes it that this is the method I have all along adopted for ordinary replicas. Such, however, is not the case, the method being as given in the foregoing particulars. Of course, considerable attention has to be paid to every part of the process, and it is only by large experience that one can produce grating replicas which are optically useful.

As stated in my letter in the current number of "Nature," I have also succeeded in making replicas of a concave grating kindly lent to me by Professor Schuster and in mounting the same on a concave surface, but as all wet methods of silvering I have tried have the effect of producing a large amount of scattered light their further production has been left over for the present.

I have mounted many of the plane films on concave surfaces, and it is found that fair definition can be obtained by them, although it is well known that the distortion prevents high-class work being attempted.

Curiously enough, although these unsilvered replicas reflect visible light very slightly, ultra-violet light to at least λ 1852 can easily be made out. This discovery was made by Mr. Morris-Airey, of the Victoria University.

The two grating replicas and two prism-gratings I send herewith are from originals of 14,438 and 15,028 lines to the inch respectively, and may be taken as good examples of my method of reproduction, the few small specks on the surface being due to dust particles and not to the method of mounting. A very cursory examination will show a considerable difference between the gratings, the one concentrating the greatest amount of light into the first spectrum on one side being taken from an original at one time the property of the late Dr. Common, whilst the other is from a particularly fine specimen of recent work on the Rowland engine. The same may be said of the prism-gratings.

In the latter case, however, it will be seen that by suitably tilting the prism the d.v. spectrum increases largely in brightness as well as dispersion, and owing to the absence of scattered light this form will probably be found the best for photographic purposes, as it certainly has been for solar prominence work, one of these prism-gratings giving a dispersion equal to five flint glass prisms in the middle of the spectrum and of course more at the red end.

I may just mention here that Sir William Abney also possesses a much larger grating than I use which has almost the same charac-

teristics as that I purchased from the late Dr. Common, and that he has been kind enough to allow me to make replicas from it on two separate occasions.

Finally, whilst admiring and welcoming the methods adopted by Mr. Wallace and others in the production of grating replicas, I have written the above with a view to substantiate my own claim to the first method of producing optically useful replicas of gratings and one which after all has not in my opinion been superseded.

THOS. THORP.

Patent News.

Process patents—applications and specifications—are treated in Photo-Mechanical Notes."

The following applications for patents were made between December 11 and 16:—

CINEMATOGRAPHS.—No. 25,735. Improvements in cinematographs. August Musger, 32, Lamb's Conduit Street, London.

FLASHLIGHT.—No. 25,750. A device for catching the smoke of flashlight lamps. Julius Fiedler and Ferdinand Hrdliczka-Csiszar, Birkbeck Bank Chambers, Southampton Buildings, Chancery Lane, London.

SHUTTERS.—No. 25,763. Improvements in photographic shutters and photographic cameras. Charles Howell and George Lloyd, 65, Chancery Lane, London.

DEVELOPING ROLL-FILMS.—No. 25,857. An improved method of and apparatus for developing photographic roll-films. William Fraser Claughton Kelly and Thomas Bolas, 7, Southampton Buildings, Chancery Lane, London.

PRINTING PAPER.—No. 25,922. An improvement applicable to photographic printing paper or films. Warwick Brooks, 4, St. Ann's Square, Manchester.

CAMERAS.—No. 25,948. Improvements in photographic cameras. Harold William Hood, 7, Southampton Buildings, Chancery Lane, London.

EXPOSING.—No. 26,191. An improved method and apparatus for the exposure of light-sensitive films, plates, and the like. Optische Anstalt, C. P. Goerz, Actien-Gesellschaft, 31, Bedford Street, Strand, London.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W. C.

CAMERAS.—No. 26,372. The invention consists of a miniature camera for roll-films, the lens, shutter, magazine, and adjusting device being all enclosed in a long straight metal tube, the sectional area of which does not materially exceed the size of the image. The adjustment for various distances is effected by shifting the film holder or magazine along the interior of the metal-tube. In Fig. 1, B is the lens, C the shutter, actuated and released by the push-buttons E and D, F is the spool-holder or magazine, and is moved to and fro for focussing the picture by means of a set-screw G or similar device inserted into a plug, cap, or disc which closes the rear end of the tube. The head H of this screw, which is situated outside the disc or plug, has a graduated circumference, showing the distance of the object in metres or yards, which corresponds to any given position of the adjusting screw. Consequently in setting the camera; the operator sees at the same time the object to be

photographed and the graduated scale. In order that the viewfinder S will not increase the height of the apparatus, it is hinged above the front end of the metal tube in such a manner that it can be turned into the front opening of the tube, and

Fig. 1.

Fig. 2.

Fig. 3.

then serves as a protective cover for the lens. Figs. 2 and 3 show another arrangement of the finder, it being hinged and attached to a folding plate. Friedrich Kalkner, Nürnberg-Mögdorf, Germany.

STEREOSCOPES.—No. 26,689, 1904. The invention is a folding stereoscope of the form seen in Fig. 1 when erected, *e e* being the lenses, one of which is mounted in a slide *m* to adjust the space between

them, or is mounted on a plate rotating from a fixed point, for the same purpose. The stereoscope folds flat, and in this shape is held together by an elastic band. Carl Pietzner, 3, Mariahieferstrasse, Vienna, II.

MACHINE PRINTING.—No. 8,816, 1905. A machine for exposing sensitive paper in the roll, the features of which are:—1. The rolls travel in light-tight conduits, so that work can be done in day-

light. 2. The entire surface of the negative is simultaneously and uniformly exposed to the light. The construction of the machine requires the numerous drawings for its explanation. Friedrich Heinrich Lange, 52b, Steinmetzstrasse, Berlin.

MACHINE DEVELOPMENT.—No. 8,616A, 1905. The inventor employs, for the support of the band of paper during development, fixing, etc., drums of adjustable diameter. On these the rolls are wound in helical windings, and developed, washed, fixed, and dried in this state. The object of such drums is to compensate for the roll stretching on becoming wet and shrinking on drying. The diameter of the drums may be adjusted by hand or automatically. Below the drums shallow dishes or trays are arranged as ordinarily, to contain the various solutions, which may be changed as often as necessary. Friedrich Heinrich Lange, 52b, Steinmetzstrasse, Berlin.

FOLDING CAMERAS.—No. 16,857, 1905. The claims are for certain features of a folding camera without projecting parts, and of a form resembling and as easily carried in the pocket as a book. *a* is the camera front carrying the lens, shutter, timing and other devices; *b* is the bellows; *f* forms the front lid of the camera when in the closed position, but when in the open posi-

sight and folding finder. (3) In a pocket camera of the kind forming the subject of the first claiming clause the combination of the camera front *a* and bellows *b* carried and guided by lazy-tongs *g g¹* running in guides *l l¹*, a sliding focussing plate

Fig. 2.

m having a spring tongue *n*, a stop *o*, hook projections *3 3x*, and operating lever *5* engaging with a fixed recessed plate *9* (Figs. 1 and 2). (4) In a pocket camera of the kind forming the subject of the first claiming clause the employment of a disap-

Fig. 3.

pearing sight *u*, spring *v*, lever *z*, and bar *w* operated by the act of closing and opening the camera (Fig. 3). A. S. Newman and Newman and Guardia, Ltd., 92, Shaftesbury Avenue, London, W.

The following specification is open to public inspection before acceptance under the Patent Act, 1901:—

PRINTING.—No. 24,964, 1905. Printing apparatus for photographic purposes. Schneider.

THE BIRMINGHAM EXHIBITION.—The twenty-first annual exhibition of the Birmingham Photographic Society will be held from February 24th to March 3rd, 1906, in the galleries of the Royal Society of Artists, New-street. The judges in the pictorial section will be Messrs. W. R. Bland, Alex. Keighley, and W. J. Wainwright. There are three open classes: 1, Framed picture, any subject; 2, lantern slides (judged singly), any subject; and 3, scientific prints or slides. Silver and bronze medals and certificates are awarded in each class, and a silver challenge cup, at present held by Mrs. G. A. Barton, is also offered for competition in accordance with a scheme explained in the entry form. This latter is obtainable from the secretary, Mr. Lewis Lloyd, Norwich Union Chambers, Congreve-street, Birmingham. The last day for entries is February 12th, 1906.

tion it forms the base or support and guiding device for the front *a* and bellows *b*, and also carries the focussing device; *g g¹* are lazy-tongs on either side of the bellows *b*, pivotally connected to the bottom of the front *a* at *h*, and to the bottom of the back *c* of the camera at *i*. They are also guided in slotted plates on the upper part of the front and back of the camera as shown at *j* and *k* respectively in the figure. The base or support *f* is furnished on either side with channel guides *l l¹* which receive and guide the pins *h h¹* of the lazy-tongs *g g¹* as the latter are being extended or closed. The channel guides *l l¹* are also furnished with other guide-ways to receive the focussing plate *m* which is adapted to slide therein longitudinally of the camera as hereinafter described; *n* is a spring tongue, and *o* is a stop, both of which are cut and raised from the plate *m*, which is also furnished with a hook-like part *3 3x* on each side thereof. The claims are: (1) A pocket camera in which the front of the camera is carried by lazy-tongs running in guides on the inside of the turned-down front lid and is locked in the open position to a focussing plate adjustable on the said front lid. (2) In a pocket camera of the kind forming the subject of the first claiming clause hereof a disappearing

Photo-Mechanical Notes.

The Bolt Court Supper.

TEACHERS, students, and friends of the L.C.C. School of Photo-engraving met on Friday evening on the occasion of the annual supper and smoking concert, which took place in one of the large rooms of Bolt Court. The gathering was of a cheerful, semi-Bohemian character. In the chair, as usual, was Mr. George Frampton, R.A., who is exceedingly popular with the students of the school, and the vice-chairmen were the principal (Mr. A. J. Newton) and the art master (Mr. Cecil Rea). After the supper the Nelson Dawson, and Frampton badge and sketch-club prizes were presented, and the chairman and most of the other speakers spoke cordially on the progress of the educational work of the school. Mr. Frampton had a few authoritative words to say on the importance of high ideals in the matter of design. Drawing from nature and life, however good it might be in itself, was not enough to make a really great artist. A picture should be a beautiful composition, and have fine sentiment and fine feeling behind it. He looked forward to the time when the school would be known and respected in all parts of the world. Much satisfaction was expressed at the fact that Mr. Frampton has undertaken to give a replica of the badge annually for ten years. Mr. H. Snowden Ward gave the toast of "The Principal and Staff," and declared that the work of the school was known and appreciated in many foreign lands. Mr. Newton received a tremendous ovation. He said the results were much better than before. He mentioned that the reputation of the school had extended to distant parts of the world. Last session they had several students from Australia and New Zealand, and recently he had received an application from India. There had been a satisfactory advance in the number of students—namely, from 373 to over 420. After thanking Mr. Dawson and Mr. Frampton for their kindness and generosity, Mr. Newton said he believed the County Council would consider the granting of a scholarship to accompany the badge. He hoped, too, that something similar would be obtained for the process side of the school.

In the entertainment which followed a dramatic performance was one notable item. It was a melo-dramatic burlesque of a very full-blooded Surrey-side piece, presented under the title "Thicker than Water, or a Murder a Minute." "R. C. Armour," said the programme, "presents F. E. Butler and his highly-trained troupe of performing students in a new and original drama in two acts," and the piece and the method of its presentation provided half an hour of concentrated and uproarious excitement. Shakespeare, Sweeney Todd, and Victor Hugo appeared to have been the founts from which the author drew most of his inspiration. Later in the evening there was an interesting exhibition of three-colour photographs, and a special exposition of lightning modelling by "Auguste Rodin." The gathering finished with the singing of "Auld Lang Syne."

Rollers for Inking Up.

A CORRESPONDENT of the "Inland Printer" in trouble with rollers used for zinc work writes as follows:—"One of them I use to ink up the bichromatised albumen print on zinc and the other for inking with good half-tone ink the etched zinc to get a proof. For a time the rollers worked well, but I notice that during the rainy season they refuse to take ink, particularly the proving ink. I keep the rollers in a box when not in use and clean them only with turpentine. Could I use rubber rollers or some composition that would not be affected by climate, which, I think, is what knocks out rollers here?" To which the reply of Mr. S. H. Horgan is:—"In my own practice, I have always used a smooth-skin, leather lithographic roller for

inking the albumen print on the zinc plate, and this is what you should use. A stiffer etching ink can be used and a thinner and even coat can be had. Even for proving, a smooth skin lithographic roller would be better in your climate. To keep the leather roller in condition it should not be cleaned with turpentine or anything that will remove the oil from it. The old or "dead" ink can be scraped from it with a palette or dull-edged knife and the roller rolled occasionally in medium linseed-oil varnish and left overnight in it. This treatment will keep the leather soft. In England they have a pneumatic roller which consists of a hollow steel cylinder, with handles like an ordinary lithographic roller. The cylinder is covered with an airtight rubber cover which can be inflated like an ordinary bicycle pump attached to an air valve in one of the handles. An outer covering of seamless red rubber, or of smooth or rough leather of any quality, can be drawn over the air cushion before inflation, and when it is pumped up the outer skin of rubber or leather will not slip and has the proper degree of hardness to work properly. The pneumatic roller with its interchangeable skins might be worth trying in this country having strong climatic changes, varying from very high temperature to extreme humidity.

Collodion Emulsion.

In the current number of "Le Procédé," a somewhat lengthy article on the above appears, from which we extract the following notes:—"Collodion emulsion has about the same speed as process dry plates. Its manipulation presents no particular difficulties. Extreme cleanliness and attention to minutiae of details are necessary, but it must not be forgotten that for half-tone work the screen distance must be altered. Another great advantage is that for three-colour work three images alone are required as against nine with wet collodion. The dark-room should be, of course, free from improper light, and also, as far as possible, from draughts, which may give rise to dust. It is advisable that the walls and benches should be varnished, so that they may be frequently washed. It is preferable to purchase the emulsion in the dry state. Fifty grammes should be mixed with about 450 ccs. of absolute alcohol, and then 550 or 550 ccs. of ether added gradually, with constant agitation, and care must be taken not to unduly expose it to the dark-room light. As, for three-colour work, it is necessary to orthochromatise, the same various dyes must be added, and omitting the use of secret dye solutions such as those of Albert and others, we come to working directions with named dyes.

CANARY YELLOW II. (READ HOLLIDAY).

Make a saturated solution of the dye in 90 ccs. of absolute alcohol, and add 10 ccs. of ammonia. To every 100 ccs. of emulsion add 5 ccs. of this solution; this will keep for several days, and gives negatives of excellent gradation and clearness from fog. After coating, rinse the plate under a tap till all trace of greasiness is lost, and then expose. There is a slight sensitiveness to yellow and green, but none to red and orange. The sensitiveness is sufficient for screen or ordinary negatives.

HOMOCOL, PINACHROM, AND PINAVERDOL.

To use these dyes a stock solution of 1 gm. in 1,000 ccs. of absolute alcohol should be made; all are used in the same way, either by direct addition to the emulsion or by bathing the coated plate. For the first method the following formula should be used:—

Emulsion	100 ccs.
Dye solution, 1:1,000	2.5 ccs.
Ammonia	5-10 drops.

The bathing process gives cleaner plates, and obviates any wastage of the emulsion, and after coating and setting, the plates should be flowed with—

Dye solution 1:1,000	10-12 ccs.
Ammonia	3 ccs.
Alcohol (90 deg.) to	100 ccs.

The quantity of solution that should be flowed over the plate is not of much moment. The solution should be gently flowed to and fro over the plate for about two minutes, and then the plate washed under the tap for three minutes and exposed.

DEVELOPMENT AND AFTER TREATMENT.

It is, of course, unnecessary to deal with exposure or the coating of the plate, but whilst Dr. Albert suggests the use of a 0.4 per cent. of acetic acid and gelatine as a substratum, the old rubber edging will be found quite satisfactory. The best, and one of the simplest, developers is von Hübl's glycin formula—

Sodium sulphite cryst.	50 gms.
Glycin	20 gms.
Potassium carbonate	100 gms.
Distilled water to	600 ccs.

For use, dilute 1 part of the above with 3 parts of water. No bromide should be used, as this tends to fog. After development the plate should be rapidly rinsed in water, and then fixed in a 10 per cent. solution of hypo, and well washed. To intensify, the best processes to use, especially for half-tone negatives, are either physical development with metal, or copper and silver. The formula for the first is—

Metal	10 gms.
Citric acid	15 gms.
Water to	1,000 ccs.

Just before use add a few drops of silver nitrate solution. For the copper bleach in—

Potassium bromide	30 gms.
Cupric sulphate	30 gms.
Water to	1,000 ccs.

Then rinse, and immerse in

Silver nitrate	30 gms.
Nitric acid	1 drop.
Distilled water to	1,000 ccs.

and generally sufficient density can be obtained, though the operations can be repeated if thought desirable. For reduction it is advisable to convert the image into silver iodide with—

Iodine	5 gms.
Potassium iodide	10 gms.
Water to	1,000 ccs.

When the image is thoroughly bleached, wash and place in a black dish, and treat with a very dilute solution of potassium cyanide, and then wash and blacken with a 20 per cent. solution of sodium sulphide. After washing and drying it should be coated with gum arabic (6 per cent. solution) or negative varnish.

New Material.

"Ensign" Sulphide Toning Cartridges. Sold by Houghtons Ltd., 87-89, High Holborn, London, E.C.

Messrs. Houghtons have placed the materials for the popular sulphide toning upon the market in a convenient dry state, each cartridge containing sufficient of the bleaching and darkening reagents to make 5 oz. of the respective baths. This quantity, it is stated, has proved ample to tone 100 quarter-plate prints, and certainly the tones obtained are excellent in every way. We judge that the bleaching powder is composed of ferricyanide and a metallic haloid, and therefore no apprehension need be felt that the cartridge contains a scheduled poison. The new preparation can be recommended as a most desirable form of sulphide toner, and as inexpensive also. A box of six tubes costs 2s., or separate tubes are obtainable at 4d. each.

New Books.

"Penrose's Pictorial Annual, 1905-6," edited by William Gamble. London: Penrose and Co. 5s.

"The Process Year Book," to give its old name, once more quite fulfils its annual function of saying and showing what is the latest work in all branches of photo-mechanical reproduction. Probably no one is better qualified for the arduous duties than its editor, Mr. William Gamble, who adds to his wide acquaintance of all process matters just that combination of criticism and enthusiasm which makes for an appreciation of progress. Perhaps we may consider that in the cases of some contributions to the volume, criticism might have well over-weighed its opposite quality and the proportionate importance of certain alleged advances have thus obtained a truer representation. However, the process worker will not cavil when he has the annual in his hands, for he will find it putting before him the latest achievements of the reproducer's and illustrator's craft. Thus the frontispiece is a specimen of power-press printed copper etching by Bruckmann, of Munich, the title page is illuminated by the spray-relief process of the Aerograph. Mr. C. G. Zander's new four-colour process is shown, as are also the Sears high-light litho process, the latest work in grain screens, in Albert's relief overlay, and in many other technical advances. The whole production is beautiful in the extreme, a credit to editor, illustrators, engravers, printers, and binders. To give a mere list of the plates and technical articles would tax our space, but we will refer in a forthcoming issue to some of the contents. Meanwhile we have only to say that to those desirous of keeping abreast of progress in reproduction methods, "Penrose's Pictorial Annual" is the one opportunity of the year.

"All About Enlarging."—An ambitious title surely for a sixpenny manual issued by Messrs. Marshall, Brookes, and Chalkley, Ltd., Harp Alley, Farringdon Street, E.C. The aim of the author, C. Winthrop Somerville, is to instruct the beginner in the making of bromide enlargements, and, *more suo*, he applies himself to his task. The necessity of brevity has led to the inclusion of some statements which can easily be misread or require qualification. For instance, we are told that "magnesium ribbon is the worst form of illuminant you can use for enlarging since it is not amenable to control." We should have thought that there were sufficient manuals of enlarging already.

SPARK Photographs.—According to "Electricity," ornamental designs in infinite variety are now drawn by the electric spark upon photographic plates. A thin sheet of lead is fastened to a cork by eight pins arranged in a circle; the pins are set upon a sensitised plate sprinkled with starch powder, and a metal sheet under the photographic plate is connected to the external armature of the Leyden jar of a Wimshurst machine, the sheet of lead being similarly connected to another jar. Passage of the spark and development of the plate complete the operation. In another method an insulating powder like starch or sulphur is sprinkled upon the sensitive plate through a design cut in cardboard, and the effects are varied not only by changing the designs, but also by laying upon the sensitive surface bits of different metals in various shapes. Different powders add to the variety, the most compact yielding the finest lines.

THE Scottish Salon.—To-morrow, December 30, is the closing day for entries for the Scottish Salon. The receiving date for pictures is January 4, and all communications should be addressed to Mr. Baird, Broughty Ferry.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

		"Home Portraiture." Mr. W. Dalton.

ACCRINGTON CAMERA CLUB.—The annual meeting was held in the Mechanics' Institute last week, when Dr. Frankish was elected president for the ensuing year.

RYDE PHOTOGRAPHIC SOCIETY.—A meeting was held last week, at the Oddfellows' Hall, for the purpose of forming the above society. Mr. Purnell was in the chair, and a large number of those interested in photography attended. Mr. M. Maybrick, having kindly consented, was unanimously elected president of the society. A temporary committee was formed to draw up the rules and report to the further meeting, to be held in about a fortnight. Due notice of this will be sent round to all whose names are already in the secretary's hands. Any other ladies or gentlemen wishing to become associated with the society will oblige by communicating with the secretary, pro. tem., Mr. Harold Senior, Hanley House, Ryde.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—Two competitions were held at the last meeting of this society, with the following result:—For a print giving the best rendering of "Peace" the silver medal went to Mr. Llewellyn White. For the best set of six lantern-slides illustrating the society's outings, accompanied with ten minutes' lecturette, Mr. H. Creighton Beckett was awarded the silver medal.

IPSWICH CAMERA CLUB.—Mr. R. H. Sutton and Mr. P. W. Elkington have resigned the posts of secretary and assistant secretary respectively; and Mr. Stanley B. Bond, of Cauldwell Hall, Ipswich, has been appointed secretary (pro tem.) in their place. At a meeting of the committee last week, the services of the retiring secretary (Mr. R. H. Sutton) and his assistant (Mr. P. W. Elkington) were recognised in the presentation by the members of the committee to each of a gold pencil case.

SOCIETY OF ARTS.—Meeting held on December 20, Mr. Carmichael Thomas in the chair.—A paper was read by Mr. Charles L. Burdick

on "The Aerograph Method of Distributing Colour," in the course of which he referred to the many uses now made by the Aerograph in the arts. For the decoration of pottery it was being used in the Government factories of France, Germany, and Denmark, and some very beautiful work was being done with it, particularly at the Charlottenberg and Copenhagen factories. The facility with which the colour could be distributed on the biscuit ware had a tendency to develop commercially the under-glaze work. In ground laying and stencilling the colours distributed with the aerograph were found to have more softness and greater brilliancy than when applied by the older methods. The method of applying colours, with the aerograph, through stencils, was dealt with, and such applications as Christmas cards, window pictures, etc., were exhibited. The small initial cost of the work enabled it to compete with litho for colour decoration, and the case was instanced of a 1,000 order for a window ticket, which, in a simple design, might require the careful stippling of three litho stones at an expense, say, of 15s. each, or 45s. Then there would be three printings necessary, say 2s. 6d. each—7s. 6d. In the case of the aerograph work—say, 6s. each—15s., four days' girls' labour, 12s. Total cost of printing by litho, £2 12s. 6d.; with the aerograph, 27s. The lecturer then proceeded to describe two machines for applying colours by aerograph, the first being one for colouring and decorative printing, for colouring photographs and other pictures. By means of the machine the cards and stencils are automatically moved and lifted, the spray of colour being likewise automatic, and the surplus colour being removed from the stencil by a system of exhaust-air. The second machine was for the continuous printing of fabrics, etc., in the roll. A series of sprays are mounted within a continuous stencil drum, around which the band of material to be coloured passes. The sprays may be used inside of or outside of the stencil. Blended shadings of colour for rainbow tints are obtained; the soft patches of various colours may be made in alignment, or the sprays may be automatically moved about, and will produce all kinds of irregular shapes; the different colours being blended more or less into each other according to the distance from the surface. As with the flat stencil, keeping the stencil clean, has been accomplished by means of suction. Air is exhausted from a tube having an opening between two blades mounted so that the opening comes near to, or in contact with, the inside of the stencil; when the air is exhausted from this tube the loose colour on the stencil is taken up and carried to a chamber. The number of colours or tints which may be employed at a single operation is only limited by the number of sprays. As constructed at present, 24 sprays are employed. In the subsequent discussion Mr. Herbert S. Starnes, F.R.P.S., instanced a case of bichromate poisoning, due to the use of a solution of potassium bichromate in the air brush, and he cautioned users as to the possible danger of pigments of poisonous properties. Mr. W. F. Reid regarded the incident as showing the valuable use of the aerograph for antiseptic purposes, and the Chairman stated that he had that afternoon visited an establishment where he found two extremely healthy-looking young ladies, users of the aerograph, in whose case he could detect no signs of poisoning.—Mr. Burdick, in replying, said they had not experienced trouble from this cause, and suggested that in Mr. Starnes's case the aerograph was used in an unventilated apartment, and with the surface receiving the spray close to the wall, in which position the spray might be reflected back on the operator.

RICHMOND CAMERA CLUB.—On Thursday, December 21, Mr. Cembrano, President of the club, delivered a lecture on "Platinotype Printing and Toning." For years past he has been advocating the use of this simple and artistic process, and hoped that an exhibition of its great capabilities might serve to stimulate members to make

further use of it. He had recently read some remarks by Sir William Abney on the treatment of platinotype paper that had become stale through age or the effects of the atmosphere, and which could be utilised and made to produce good soft effects by printing it out and then fixing it in warm water. In order to test this Mr. Cembrano placed some platinotype paper in a drawer where it could become damp instead of keeping it dry in a calcium tube, and after some days he commenced printing operations. As this work was done in November the prints took several days to print out, and consequently all conditions were entirely at variance with all orthodox ideas on the subject. Prints made in this way were cut into pieces, and the different parts developed by different processes—hot water, weak developer, and ordinary developer, with the addition of different restrainers. The pieces were then mounted together for comparison. Mr. Cembrano showed a number of these experimental prints, amongst which were some very satisfactory results. He then proceeded to show prints made on this paper in the ordinary way, and also from the same negatives exposed under green and yellow glass, the effect of the coloured glass being to reduce contrast and greatly to soften the picture. Another process which he explained was the production of coloured prints by the addition of mercury to the developing bath and by toning after development. By the former process a sepia colour is produced, and by the latter a great variety of colours, sepia, various shades of red, and a variety of blues, may be obtained at will with the same toning bath. Specimens showing these results were handed round, and Mr. Cembrano gave the formulae by which they were produced. At the conclusion of the lecture a hearty vote of thanks was passed unanimously.

Dews and Notes.

DEATH OF H. A. Hyatt.—The sudden death of Mr. H. A. Hyatt adds one more to the long roll of removals from the American photographic world during this past year. Mr. Hyatt was the founder and president of the H. A. Hyatt Supply Company, of St. Louis. For many years the business went under his name entirely, and he had made a splendid record with his ability and untiring push.

A PHOTOGRAPHIC competition is announced by "The Animal World," which offers monthly prizes for photographs of animal subjects. All photographs sent in must be of this class, and must depict an incident or story. Natural and successful grouping will be taken into consideration when judging the merits of each photograph.

MORE Breathless Photography.—"The Australian Photographic Journal" has related one or two instances of very rapid work in connection with cinematography, remarking that Australian photographers have proved themselves equal to high achievements when the occasion calls for their best efforts. The latest record is as follows:—At the "world's champion" rowing contest between Stanbury and Towns, held on the Paramatta River, Sydney, last month, between the hours of four and five o'clock, a cinematograph machine was operated on the race, and the films displayed the same evening. The fine definition and general good qualities of the pictures call for special commendation.

How to Start a Free Portrait Business.—Among the letters addressed to Madame Hofer, the recent winner of the million francs lottery prize, there is one published by the "London Magazine" this month which we may reprint as showing the class of plausible rogue who is responsible for the deluge of circulars offering free enlargement. The letter runs:—

"Allow an old soldier who suffered in Paris during the siege and the horrors of the Commune, and who, after fourteen years of military service, has been for 27 years past in the priesthood, and is at the moment officiating priest in the poor parish of—, allow me, I say, Madame, to be one of the first to congratulate you. With the intention of repairing my poor country church I am connected with artists for the enlargement of photographs."

And he encloses a circular, stating that for five francs one can have his or her portrait enlarged. After a long eulogy on the beauty of the enlargements he cautions Madame against any Paris firm which promises a photograph for nothing, and then makes customers pay for the frame. But should Madame want a frame, he can supply it for ten francs.

Next he points out that as the Government does not tax her prize, she saves 80,000 francs, and suggests she might be generous enough to send him 20,000 francs, so that he can send out a further two million circulars and increase the photographic business. As an inducement to her generosity, he adds:—"Be assured Madame, that the good God, who let you win the million, expects from you great generosity for His good works. God has established you as His stewardess; consequently the Divine Providence will continue to confer on you His blessings and favours."

He promises to pray for Madame, and to make his flock pray also, every day, if she makes him a good present that will enable the church to be restored; and asks also, can't she send 300 francs, that Mass may be said three or four times a week—Sundays and holidays excepted—for the poor souls in purgatory.

Then, in case Madame doesn't want photographs of herself or her friends enlarged, he has wine to sell. "Vin de Lourdes. It is a tonic, or natural dessert wine. By its name it is known; the bottle from its label can be placed on any table." And if the wine fails to appeal, M. le Curé has preserved truffles, peaches, and tomatoes for sale at ridiculous prices!

Commercial & Legal Intelligence

AT BOLTON, Arthur Graham Stevens, clerk, and John Gettings, photographer, have been committed for trial for obtaining goods from tradesmen by false pretences. According to a statement made by Stevens the men had been convicts at Dartmoor together, and while there, Stevens being orderly at the Roman Catholic Chapel, both were punished for a too free use of the sacramental wine.

UNAUTHORISED Reproduction.—An action, briefly reported in our last issue was brought by Mr. Arthur Hamilton Lee, M.P. (late Civil Lord of the Admiralty), and Mrs. Ruth Moore Lee, his wife, against Lafayette, Limited, the registered office of which is in Dublin (1) for an injunction to restrain the defendant company, its officers, servants, and agents from publishing or allowing or authorising to be published, and from selling or offering for sale, or exposing by way of advertisement, or otherwise, or any way dealing with any photographs of Mrs. Lee taken by the defendant company; (2) for delivery up of photographs and negatives. Mr. Astbury, K.C., and Mr. Mark Romer now moved for an injunction to restrain the publication or sale of Mr. Lee's photographs. In 1902 Mrs. Lee in the ordinary way attended on the defendants in New Bond Street and had some photographs taken. She paid for these in the ordinary course, and nothing was said about the copyright in the photographs, but neither she nor her husband ever authorised the defendants to publish or sell the negatives or any pictures reproduced from them. In September, 1905,

a portrait of Mrs. Lee, taken from one of the defendants' photographs, appeared in "The King," and, according to the evidence of the defendants' London manager, he assumed that the plaintiffs had given leave to reproduce the portrait from a photograph, and, thinking that Mrs. Lee would not object to her photograph being published in other papers, he sent several copies to some of the leading papers. From one of the photographs a reproduction appeared in "Black and White" on November 11, 1905. On November 15 Mr. Lee saw the manager and complained of the publication of Mrs. Lee's photograph without consent, and the manager thereupon expressed his deep regret and promised that such publication should not occur again, and that steps would be taken to repress it. Notice was then sent (as was believed, to all the papers which had accepted the photographs) not to publish, but to return the photographs, but it was apparently forgotten that a photograph had been sent to "Madame," and it appeared in the issue of that paper for December 2. Mr. Buckmaster, K.C., and Mr. Ashton Cross appeared for the defendant company. Mr. Buckmaster expressed the regret of the company that publication of Mrs. Lee's photograph had taken place, and said the company were willing to pay the costs of the proceedings and to give the plaintiffs all the relief to which they were entitled. The learned counsel referred at some length to the evidence filed on behalf of the defendants, in which it was stated that quite nine out of ten of their most aristocratic sitters gave a general leave for reproduction of their photographs. Mr. Justice Buckley: Does it not come to this, that vulgarity is so great that they are entitled to assume that everyone is vulgar? Mr. Buckmaster, continuing, said that defendants had made a mistake and regretted it; they were very sorry that they had caused annoyance to the lady, and apologised, and were quite willing to pay the costs. If Mrs. Lee wished to have the negatives they would be given up. Mr. Justice Buckley said that defendants had taken photographs of a lady for which they had been paid, and the copyright in the photographs belonged to her. Having seen one of the photographs reproduced in "The King," the defendants drew the conclusion that they were entitled to sell some of the photographs for profit. Accordingly, some of the photographs were sent round to papers, and one of them was published in "Black and White" in November. The lady's husband was indignant at this, and called on the defendants and complained. Shortly afterwards one of the photographs appeared in "Madame." His lordship said he accepted the defendants' explanation as to this. They had attempted to stop further publications, but did not remember that a photograph had been sent to "Madame." The offence lay in the unwarrantable assumption that, because a portrait had appeared in "The King," the defendants were entitled to let other photographs be published. His lordship was sorry that it should be supposed that because the age was so vulgar the lady was a party to the vulgarity of the age and allowed her portrait to be published. The defendants undertook to pay the costs of the action and not to publish further, and offered to give up the negatives and any photographs of Mrs. Lee in their possession.

FAILURE of a Photographic Expert.—The first meeting of the creditors of William Thompson Wilkinson, photographic expert, 335, Brockley Road, S.E., took place at the offices of the Official Receiver for the Greenwich district on Thursday in last week, but no resolutions were passed, and the estate will consequently be wound up by the Official Receiver in the usual manner. The statement of affairs filed by the debtor disclosed gross liabilities amounting to £223 9s., of which £218 17s. 4d. was due to unsecured creditors. The assets were estimated to produce £95 10s., from which £4 11s. 8d. had to be deducted for the claims of preferential creditors payable in full, leaving the net assets at £90 18s. 4d., and disclosing a

deficiency of £127 19s. From the statements made by the bankrupt at his preliminary examination it appears that he is a photographic expert, and is employed as a teacher of photography at the Goldsmiths' College, New Cross, at a salary of £100 a year, and that in January, 1905, he commenced business with a capital of £80 under the style of the Uni Photo Company at 335, Brockley Road. He alleges that his son, Mr. E. J. F. Wilkinson, was a partner in that business, and on August 1 last his son took over the business on the verbal understanding that he (the son) should provide the money to pay the then existing liabilities. The bankrupt alleges that on November 1, 1905, the son, without his consent, removed the whole of the trade goods and other effects from 335, Brockley Road to 314, Queen's Road, Peckham, where the son is now carrying on a business of the same nature. The fact that there was a partnership is denied by the son, who states that up to August 1 he was simply in the employ of the bankrupt, and he then took over the stock, in respect of which he has made payments to or on behalf of his father. The accounts are not satisfactory, and the bankrupt has been requested to amend and amplify them, and to grant delivery of the book of accounts relating to his business.* The whole of the furniture at 335, Brockley Road, is claimed by the bankrupt's wife as her separate property. The bankrupt's unsecured liabilities, which are stated to have been contracted between December, 1904, and the date of the receiving order, are almost entirely in respect of goods supplied and work done. The bankrupt attributes his insolvency to "The action of my son in surreptitiously removing the assets belonging to the partnership existing between us and his repudiating the arrangement made for the provision of the money required to pay the debts incurred prior to August 1, 1905." The bankrupt has filed a deficiency account setting out the following particulars:—Excess of assets over liabilities on January 1, 1905, £80; salary as teacher of photography since January 1, 1905, £85; other earnings as photographer, £58; deficiency at the date of receiving order, £127 19s.; total, £350 19s., which amount is accounted for as follows:—Estimated household expenses of self and wife since January 1, 1905, £90; depreciation in value of effects as estimated for realisation, £43 16s.; balance unaccounted for, owing to my son having taken away the books of partnership, £217 3s.

BUSINESS WASTE.

To the Editors.

Gentlemen,—I was much interested in reading your article on "Business Waste" in your last number of the JOURNAL, in which you refer to the necessity of closing up one's books and getting out a balance-sheet at the end of the year.

From my recent experiences, while trying to purchase a photographic business, it would appear to be the exception for a professional photographer to balance his books at all: in the majority of cases the excuse for not being able to produce a balance-sheet and profit and loss account has been that the individual is not a "business man," and has no head for figures, but this seems to me a very poor excuse.

In every case the sellers are content with giving an estimated sum as "takings," but are quite unable to say how much profit has been

ade. In one case where the "takings" were from £1,100 to £1,500 the profits turned out to be practically nil, and yet the seller was making a very large sum for the goodwill, etc., of such an affair.

To my mind a photographer (like any other business man) should be able to show year by year the profit he has made, or it will in the end very surely happen (like the case in your last number) that he will find he has been bankrupt for a considerable time without knowing it!

The matter would right itself if no one would buy a photographic business without seeing a profit and loss account.—Yours faithfully,
AN AMATEUR.

THE COBALTAMINE REDUCER.

To the Editors.

Gentlemen,—In reference to your review of "Sanzol" in this week's issue, we should be glad if we may say a few words on one or two points that we think may be of interest to some of your readers.

First, with regard to your remarks about the use of acetic acid or acidifying "Sanzol," it is still our opinion, as was mentioned in the "Photographic Journal," May, 1905, p. 188, that organic acids with these types of cobaltamine compounds are too slow in action to be of much practical use. We cannot say that we recommend the use of acetic acid ourselves, for this reason especially—that a reducing solution so made tends to deposit a comparatively insoluble cobaltamine compound on the film, which generally necessitates more than three minutes in the ammonia bath for its proper removal after reduction. We trust that it is not your opinion that the use of nitric acid of 3 per cent. strength (as we recommend) does not give a reducer well under control, as this is one of the points that we feel that we can lay stress on, viz., that "Sanzol," used according to the instructions sent out with it, is extremely even in its action, and its action is well under control. Secondly, we might perhaps also mention that we recommend the use of the dilute ammonia bath, not to arrest the reducing action (as sodium sulphite is used with ammonium persulphate), but to clear a slight amount of a silver cobaltamine compound formed in the film during reduction. After many experiments we have come to the conclusion that ammonia is the safest and best agent, all things being considered, for this purpose, as it at the same time quickly and harmlessly neutralises any acid in the film, forming an extremely soluble salt, thus shortening the time for the final wash. Indeed, we consider that in this case the use of the dilute ammonia bath after reduction leaves the negative as near as possible to the ideal of "Pure silver in pure gelatine."—

H. EDMUND AND CO.

Columbia Road, London, E.

December 22, 1905.

[It was not our desire to suggest that the reducer as compounded with nitric acid was unmanageable. A weaker acid appears to us preferable, particularly for paper prints, but we are glad to have Messrs. Edmund's caution as to the additional care in using it.—
Ems., B.J.P.]

"HISTORICUS."

To the Editors.

Gentlemen,—I suppose we all feel somewhat sad in parting with an old friend, especially those of us who, like the writer, have long passed the "meridian" of life; therefore it is with feelings of regret that I, for one—and doubtless there are many others—bid adieu to our old friend "Historicus," who has recalled to us the days of our youth upwards through many changes in the photographic world. I have watched his "Week in History" with great interest, having started in the profession at the time when James Glaisher at the

Greenwich Observatory, Geo. Shadbolt (was he not connected with your journal?) and such men were to the front, and many an honoured name has he brought to my remembrance. But there is one of the early workers I fancy has been rather overlooked—I refer to Dr. Hill Norris, of Birmingham, who brought out the first dry-plate process, I think, about forty-five years ago, or it may be a little longer; at all events I used a large number of them at the time, taking a series of the London club houses 11 by 9, and assisting the late A. J. Melhuish in taking a series of 16 by 12 round the Isle of Wight, and many others. The drawback to them was the long exposure required—2 to 3 min. and more for a medium size—but the results were very good, far better than many I have seen taken with the present plates. They seemed to have more of the qualities of the wet plate, with, of course, the exception of speed. But I have somewhat digressed. My object in writing was to thank our old friend for his shadows of the past; and may I conclude by wishing editors, contributors, and publishers a happy and prosperous New Year.—Yours deeply indebted,
J. P. STARLING.

97, Oxford Road, High Wycombe.

December 26, 1905.

THE PROPOSED COPYRIGHT BILL.

To the Editors.

GENTLEMEN,—Somebody is trying to "rush" us. Who is it? I notice in the proposed Bill that the photographer is not entitled to his own production unless it is unmistakably stamped with his name and other particulars. Now, this does not help the photographer one iota, but it does make it easy for him to be robbed.

In America they have a copyright law which puts photographers at the mercy of unscrupulous people, and that law contains a clause similar to the one I protest against. I will explain how the proverbial coach and four drove through the law, and over the photographer, by a short true story. Some years ago I was publishing an annual for an American newspaper, and in my search for a suitable supplement I obtained a beautiful portrait of a beautiful lady, which I had reproduced by a pure photographic process. Mark the result! A firm exploiting a patent hair-wash took that picture, and used it broadcast in their advertisements. When we sought to restrain them they produced a mounted photograph, and triumphantly showed that there was no indication of copyright or ownership on either picture or mount. Why, it may be asked, had the photographer omitted to do this? There lies the iniquity. That photograph was one of the actual ones which had been published with the Annual, and beneath it, when published, were all the statements required by law. The Hair people had cut away the margin and mounted only the print on an ordinary cabinet mount!

Now, sir, one warning, and I have done. In America the Press has shown itself hostile to any change in a Bill which is so strongly in its favour; in this country the illustrated newspaper is not the large factor it is there, but it is sufficient to give practical support to the Bill, and doubtless at least a section of it will do so. If we are to hold our rights we must be up and doing.—Yours faithfully,
"BROOKLYN."

December 22, 1905.

FRAUD ON PHOTOGRAPHERS.—At Plymouth, on December 18, William Henry Guy, printer, 9, Central-street, was charged on remand from the 13th inst. with obtaining 1s. by means of false pretences from Ellen Morrell, Mead Villa, Western College Road, on December 4, and, further, with embezzling 3s. on November 30, 2s. 6d. on December 5, and 3s. on December 2, belonging to Messrs. Major and Darker, photographers, Union Street.—Prisoner was awarded two months' imprisonment with hard labour.

Answers to Correspondents.

- * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

J. Weir, Burn Cottage, Moffat, N.B. Photograph entitled "Resting by the Way."
G. S. Cousins, 30, Butter Market, Bury St. Edmund's, Suffolk. Photograph of Capt. Hervey, R.N.

H. Rusholme, Petergate, York. Photograph of Minster Gates and Minster, York

THE AEROGRAPH.—1. Kindly favour me with an address for best book on air-brush finishing (B. and W.) portrait enlargements.
2. Also good cheap house for bromide prints.—CORNISH.

1. We know of no book on air-brush work. 2. It is contrary to our custom to recommend particular firms. Consult our advertisement columns.

A SUMMONS QUERY.—When a traveller calling on small shopkeepers up and down the country taking orders for postcards opens an account that is difficult to collect, is it correct to take out a summons in the district where the firm supplying the goods is situated, say London, or should the summons be taken out at the county court of the district where the customer resides? The former is, of course, the easier method if correct. I have understood that if the customer signs an order for the goods on which is printed "All accounts payable in London," or if these words are on the invoices used by the firm, in that case proceedings can be taken for recovery of the debt in a London court. Is this so?—F. PENNY.

The summons is taken out in the district of the supplying firm.

FIXATIVE FOR PASTEL WORK.—Some time ago in the JOURNAL there was an article giving a special formula for a fixing medium for crayon and pastel work. I made a note of it at the time, but cannot now lay my hand upon it. If you can inform me of the formula now, I shall be very much obliged to you.—F. R. M.

The following is the formula (which you will see among those for "working up prints" in the "Almanac") :—(A) mastic, 24 grs.; amyl acetate 3 oz. Dissolve by agitation and allow to stand some hours before use. (B) Celluloid (film clippings free from emulsion will do), 7 grs.; amyl acetate, 3 oz. Dissolve by agitation. Mix when both are clear, and keep in tightly corked bottle. Apply with spray diffuser.

SULPHIDE TONING.—1. Can you please give me a good formula for the sulphide-bleaching method of toning bromides. I have seen a lot of these recently, but I am in doubt as to which to try. I see an iodine formula spoken well of, or do you recommend the copper process? Your kind assistance will

greatly oblige. 2. Can the process be used for prints on t. gaslight papers?

1. The iodine method is expensive, and not so certain as the others. The copper bromide method is not as good as the following :—(A) Ammonium bromide, 300 grs.; potassium ferricyanide, 300 grs.; water, 20 oz. (B) Sodium sulphide (pure), 100 grs.; water, 20 oz. Bleach the fixed and washed print in A solution. Wash for a few minutes in water, and then immerse in B solution until toned. The print is then washed and dried. 2. Yes.

F. A. WOOD.—State your requirements to Mr. Jonathan Fallowfield, 146, Charing Cross Road, London, W.C.

THE Enlargement Swindle.—At the Andover Police Court George Dorman, alias Lawrence, photographer, of New Street, Andover, was charged with obtaining by false pretences various sums of money from different persons in the district for enlarged photographs that had never been supplied. The prisoner pleaded not guilty. A number of witnesses stated that the money paid by them to the prisoner was for enlarged photographs, which they had not received, neither had prisoner returned the money to them. P.C. Cox stated that he apprehended prisoner on December 4 on a warrant at Rowton House, Hammersmith. In reply to the charge, prisoner then said, "I don't think there is any fraudulent intent." Mr. Phillips (for the defence) contended that it was a case for the County Court. Prisoner elected to have the case dealt with summarily, and pleaded not guilty. The Chairman said the Bench considered him an unqualified blackguard, and that he took the money without any intention of ever doing the work. The sentence of the Court would be two months' imprisonment with hard labour on each charge, or four months altogether.

FAILURE of a Bournemouth Photographer.—Robert James Scott, 292 and 294, Holdenhurst Road, Bournemouth, photographer, appeared for his public examination at the Poole Bankruptcy Court on Wednesday, before the Registrar. The summary of accounts filed by the debtor showed liabilities estimated at £224 3s. 6d., of which £216 19s. 6d. was expected to rank for dividend, and assets returned at £32 16s., leaving a deficiency of £184 3s. 6d. Bankrupt attributed his failure to "loss in connection with the photographic business at Boscombe in 1903, bad trade, and illness of self, wife, and children." He commenced business as a photographer at the address given about twelve years ago with practically no capital. He subsequently opened a branch business at Boscombe, and in twelve months lost over £100. In 1900 he also commenced business as a furniture dealer at 294, Holdenhurst Road, employing a man to attend to this shop, and he found the business did not pay. He gave up the photographic business in October last. He stated he only became aware of his insolvency six months ago, but his deficiency account showed that his liabilities exceeded his assets by £78 a year ago. The examination was closed.

* NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

Charge for PREPAID ADVERTISE-
MENTS of Four Lines (each Line
containing about Seven Words)
of the following Classes ONLY:

Photographers Requiring Assistants
Operators, &c., Wanting Situations
Photographic Premises to be Let or Sold
Second-hand Photo. Apparatus for Sale
Miscellaneous Trade Announcements

Each Additional Line, Sixpence.

1/- Each Insertion Not Prepaid.

Those wishing to have their Advertisements addressed to initial letters, &c. **BRITISH JOURNAL** replies; but no charge is made if letters are called for.

DEPOSIT.—When dealing with strangers our Deposit System renders the transaction safe, and the fee is trifling compared with the protection thus afforded. The purchaser's money must be deposited with **HENRY GREENWOOD & Co., 24, Wellington Street, Strand, W.C.**, and all Cheques, Money Orders, &c., are to be made payable to them. Acknowledgment is sent to both parties. The goods can then be sent on approval, and we hold the deposit until hearing they have been received and found satisfactory, in which case the amount deposited is forwarded to the seller, less one shilling for out-of-pocket expenses. If goods are not approved we shall bring them back to the sender as to their sale return before refunding the deposit, the usual fee of one shilling being deducted. Goods to be sent direct to the prospective purchaser immediately upon receipt of our advice note, and all disputes or questions arising must be settled between the contracting parties.

SPECIAL NOTICE.—THE LATEST TIME FOR RECEIVING SMALL ADVERTISEMENTS IS 2 O'CLOCK P.M. ON WEDNESDAYS for insertion in the current week's issue.

LARGE ADVERTISEMENTS should reach the Publishing Office not later than Tuesday.
* Communications relating to Advertisements and general business affairs must be addressed to **HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.**

Situations Wanted.

* In applying for Situations where specimens are sent, it is preferable that they should be unmounted. In any case, the owner's name and address should appear on the front of each photograph, which would avoid confusion and facilitate return. Postage for return of specimens should always be enclosed.

* THE Professional Photographers Association is now prepared to grant Certificates of Competency to Operators, Printers, &c., on the testimony of present and past employers. — for particulars apply to the Hon. Secretary, 51, Baker Street, W.

ADVERTISER, F.R.P.S., desires Position as Manager and Operator, London; many years' experience. —Address J. Percy, 12, Drayton Green Road, West Ealing.

AS First-class Carbon and Plat. Printer, sepia, black, and toned, or as Retoucher; good with knife; highest refs. If in London, part time would suit. —Address K. 10, 24, Wellington Street, Strand.

AN Operator and Retoucher desires Engagement in good-class studio; willing to assist generally; moderate salary for permanency; (no Sunday work). —J. J., 20, Henry Street, Rochdale.

AS Manager in provincial house; excellent all-round experience, including enlarging and finishing in B. and W. and water colour. —"Omega," 87, Priory Road, Hastings.

ASSISTANT requires Berth; five years' practical all-round experience, studio and dark room, and accustomed to bromide enlarging, etc. —Apply S. B. Aldworth, Bursleigh, Richmond Park, Bournemouth.

ARTIST, Operator, Manager.—Gentleman, of highest ability and experience, seeks Position with high-class firm. —Address K. 8, 24, Wellington Street, Strand, London.

AS Printer in Carbon, Plat., Matt, Silver; can operate and enlarge if required. —Address "Printer," 80, Palace Road, Bromley, Kent.

AS SMART Studio Assistant, willing to assist all round, Continental and West-End exp., can retouch, desires Post as above; moderate salary for permanency. —"A. N.," 3, Ship Street, Brighton.

GENTLEMAN, all-round photographer, having his own whole-plate outfit, expert in architectural and copying work, desires Engagement; speaks, English, German, French, and Dutch fluently. —Address K. 6, 24, Wellington Street, Strand.

GOOD All-round Assistant disengaged (January 1st). —F. W. Hurlford, 4, The Green, Crediton.

OPERATOR, experienced, disengaged; very successful portraitist; exceptionally clever with children, electric lighting, and retouching. —Barton, 3, St. Lawrence Road, Moseley Road, Brixton, S.W.

OPERATOR-RETOUCHER desires Re-engagement on January 1st, or as General Assistant; well up in all branches of the profession. —E. E. Prangnell, 174, Windham Road, Bournemouth.

OPERATOR-RETOUCHER; quick trade; could manage; age 28; experienced; 30s. —Address K. 7, 24, Wellington Street, Strand, London.

OPERATOR-RETOUCHER desires Post; generally assist; could manage branch; 11 years' ref.; London or suburbs. —H. Burnham, 20, Costa Street, Peckham, S.E.

OPERATOR-RETOUCHER of ability open to Engagement; artistic lighting, posing, clever with children, etc.; first-class refs.; no spec. —"Operator," 57, Gurney Street, New Kent Road, London, S.E.

BURROUGHS WELLCOME AND CO.

LONDON, SYDNEY, CAPE TOWN AND MILAN

[COPYRIGHT]

RIGHT NOW.

Now is the time to look into the matter of your cash system. Now the rush of "before-Christmas" business is over, you have got more time to give to this vital part of your business.

If you have got to make any change, you want to do it now, and get it fairly started before the rush of Spring business.

We maintain that our National Cash Register for photographers will save you money by preventing mistakes in cash, and keeping a splendid system on your business.

No human being can carry out a business system in the way a machine will do it.

Post the coupon to-day, and we will give you full particulars free.

Cut along this
line.

COUPON.

TO THE NATIONAL CASH REGISTER CO., LTD., SYSTEMS DEPARTMENT,
225 & 226, Tottenham Court Road, London, W.

Please give me full information about your National Cash Registers for Photographers, and show how they would save money, and provide a check and system for my business.

I do not undertake to buy anything; I only ask for free information.

Telegrams: "Photolol," London.
Telephone: 1164, Hammersmith.

Few photographers can seriously study optics, but the proof of the pudding is in the eating, and all may prove that among lenses the simplest means are best, by comparing Cooke lenses with any others. We willingly send Cooke lenses on trial. Knowing that their merits, which result from simplicity of construction and rare accuracy of workmanship, will ensure decision in their favour.

Write us or ask your dealer.
